The Bill for the amalgamation of the Baker-street & Waterloo, the Great Northern, Piccadilly & Brompton and the Charing Cross, Euston & Hampstead Railways was considered last week by the Committee on Unopposed Bills of the House of Commons.

Mr. Bonner Maurice, agent for the Bill, explained that the companies had been working practically as one for some time, and the object of the Bill was to bring about a complete amalgamation of the three companies.

After a brief discussion of the question of workmen's tickets, the Bill was passed and ordered for third reading.

BAKER STREET & WATERLOO RAILWAY BILL.

On Thursday last week this Bill came before the Committee of the House of Commons on Unopposed Bills. In the Bill power was sought to make a subway at the Oxford-circus station. It is intended to construct a moving staircase, or escalator, 120 ft. long, from the station platform to the street level, by which passengers will be able to ascend without waiting for the ordinary lifts. The escalator is in operation in America, but this is the first application of the principle by an English railway. The plans for the proposed work require the approval of the Board of Trade. The Bill was ordered to be reported for third reading.

WIMBLEDON & SUTTON RAILWAY BILL.

The Select Committee of the House of Commons (presided over by Mr. Ashton) last week found the preamble of this Bill proved.

GLASGOW GAS CONSOLIDATION BILL.

A House of Lords Committee, presided over by the Duke of Bedford, has passed the preamble of this Bill. The Committee allowed the Corporation to create a reserve fund for their gas undertaking, but refused to grant power to devote surplus gas profits to relief of rates. The Corporation have also obtained authority to charge differential rates in favour of large consumers.

HANDSWORTH URBAN DISTRICT COUNCIL BILL.

On Tuesday this Bill, which authorises the construction of additional tramways, &c., came before a Select Committee of the House of Commons. Opposition was offered to certain clauses by Birmingham Corporation who are promoting a bill for the extension of their area. The Committee, however, decided to postpone the consideration of the Bill for a fortnight, or until a decision was come to on the preamble of the Birmingham Extension Order.

CAMBUSLANG and ARDROSSAN ELECTRIC LIGHTING ORDERS.

On Friday a House of Commons Committee (presided over by Sir H. Kimber) considered the bill for confirming the Provisional Order promoted by Lanarkshire County Council for an extension of their electric lighting area at Cambuslang. The Caledonian Railway Co. sought to have a protective clause inserted providing that any additional expense that might be incurred by the company when rebuilding or altering their bridges carrying roads over the railway by reason of the existence of the electric cables of the County Council should be repaid by the County Council.

Digitized by Google

On behalf of the promoters it was contended that if any alteration or modification of the general law regulating electrical undertakings were necessary it ought to be dealt with in a public general act and not in a local order.

The Committee decided that special protection should not be given to the company under the order, but the Chairman expressed the opinion that if the point had come up as a general question, as it doubtless might in the future, great consideration would have to be given to both views.

The same decision applied to the Ardrossan Electric Lighting Order.

Metropolitan Railway Bill—Last week the Unopposed Private Bill Committee of the House of Commons passed this Bill, which authorises the Metropolitan Railway Co. to acquire additional lands for their undertaking, to construct (in conjunction with the City & South London and the Great Northern & City Railways) a subway at Moorgate-street connecting the stations of the three companies, and to enlarge and improve Baker-street station, &c.

London Electric Supp'y Bill.—Mr. Brunner, Mr. James Parker and Sir Thomas Hickman have been nominated members of the House of Commons Select Committee to consider this Bill.

LEGAL INTELLIGENCE.

Neals & Lyons v. City of Birmingham Tramways Co. (Ltd.)

On Friday last Mr. Justice Swinfen Eady heard a motion on behalf of Messrs. W. Neale and Mark Lyons for an injunction against the City of Birmingham Tramway Co. and Messrs. E. Garcke, J. A. Christie, G. C. Cunningham, C. Hilton and J. A. Lycett (directors of the company) to restrain them from acting on a resolution passed at an extraordinary meeting of the company on May 19 last (and confirmed on June 9) that out of the accumulated profits of the company £4 per share be paid to the holders of 6,047 fully-paid ordinary shares of the company by way of reduction of capital.

Mr. Buckmaster, K.C. (with whom was Mr. Tyldesley Jones), for plaintiffs, contended that the resolution was ultra vires. That was not a reduction of capital. It was a resolution which purported to be passed under special powers obtained first by an act of 1880, and next by an Act of 1908, enabling the company by special resolution to return its capital.

His Lordship: By the reduction of the capital?

Mr. Buckmaster said the real question was whether the powers conferred by the statute enabled the company to pass the resolution returning to certain members only of one class of shareholders money that had been paid up on their shares. Plaintiffs' submission was that they did not, and that the statute only permitted the return of money to all classes of shareholders, and not to certain members only. The motion would be treated as the trial of the action. The object of the resolution was to alter the rights of the ordinary shareholders who had paid in full, so that with regard to future dividends they should stand on the same footing as those shareholders with only £1 paid up. That was a resolution which could not be passed under the section, the essential feature of which was that the money which was capable of being returned was money which must be available for distribution as dividend among the shareholders.

Mr. Gore Browne, K.C., for the company, contended that the resolution was in accordance with the rights of the shareholders under the Act of Parliament. The company had power to return a portion of its profits to its shareholders in accordance with their rights in the capital of the company. If that were lawful, the Court could not interfere.

His Lordship, in giving judgment, said the holders of the 6,047 shares complained of the resolution, their point being that the remaining ordinary shareholders were using their voting power to resolve that the 6,047 shareholders be repaid £4 per share, to the intent that those shareholders who had received the full dividend on their £5 might henceforth receive a dividend on only £1; and they contended that the case was not within sec. 40 of the Companies' Consolidation Act, 1908. He had no discretion to exercise in considering whether the company ought or ought not to do what they now proposed to do. The only point for him to consider was whether they had the legal power to do so. The sum to be returned was a sum of undivided profits, which, with the sanction of the shareholders, might be distributed among the shareholders in the shape of dividend or of bonus. In his opinion this particular form of repayment was allowed by the Act, and therefore the motion failed. His lordship added that though that might appear somewhat hard on the shareholders who objected, they had taken their shares subject to that liability being paid off.

The motion was accordingly dismissed, with costs.

Metal Filament Lamp Patents.

On Friday last the action of Osram Lamp Works (Ltd.) v. G. M. Boddy & Co. came before Mr. Justice Parker on a motion to discharge an order for trying the case with reference to two patents in the same action.

Mr. Bousfield, K.C., who (with Mr. T. Terrell, K.C.) appeared for defendants in support of the motion, said his application was to discharge an order made in chambers joining the two patents in one action. The question that arose was entirely a question of the convenience of the trial and was not with them a mere question of costs. Defendants objected to the two patents being litigated together, because that course would involve a great deal of difficulty. The real question was how far it was convenient or even desirable with reasonable lucidity to try the two questions together. The action was brought originally on one patent—the general patent of principle. Then a summons was taken out for leave to amend the writ so as to include a second patent, and leave was given. That patent dealt with an entirely different matter to the subject of the first patent. The first related to the manufacture of metal filaments of tungsten, the principle being to mix a metallic powder with carbon, then chemically to discharge the carbon and so obtain a filament of tungsten. The second patent related to the attachment of the filaments to the "leads" that went through the glass. He submitted that the manufacture of the filament and its method of attachment were entirely different, and depended upon entirely different considerations. It was not at all probable that the evidence given at the trial with reference to the one patent would have any reference to the other patent. The joining of the two might result in the saving of a little in cost, but that was not the important matter. The two patents were owned by plaintiffs, and the defendants were the same in both cases and the lamp was the same lamp, but in the first case the allegation was general and in no way was the connection of the filament included. The connection was alleged to infringe another of plaintiffs' patents which was entirely different. Under those circumstances he submitted there was sufficient difference to induce his lordship to say that it was not a good thing to bring the two together in one action. The alternative he suggested was to let the two actions go on together, and try first the question in the one case and then the question in the other. The plaintiffs had chosen to divide them at the start, and though he saw the expediency of them coming on side by side and the distinct advantage of both being tried by the same judge, the specifications confirmed the totally different nature of the two claims, and he contended they should not be joined in one action.

Mr. Walter, K.C., who (with Mr. Colefax) represented plaintiffs, said that both patents were in connection with a particular filament. The second patent related to the amalgamation of that particular filament with another metal so as to form the lead. The evidence must necessarily be much the same in both actions. The same experts would be called and the general history of the thing would be the same. The two patents were owned by the same plaintiffs, the actions were against the same defendants and had reference to the identical filament. The question would largely involve the properties of tungsten, and there would be a very large saving of time and cost if both the patents were tried together.

Mr. Justice Parker said that he was not satisfied that any essential inconvenience would be caused by trying the two actions together and prima facie it was convenient that they should be tried together. He dismissed the application, with costs.

Tramway By-Laws.

Before a Divisional Court last week a motion was made on behalf of the National Motor Carriage & Horse Owners' Accident & Insurance Union, for a rule nisi calling on Manchester Corporation to show cause why a writ of mandamus should not be issued requiring them to frame by-laws under the Manchester Corporation Tramways Act, 1900.

Mr. Forbes Lankester, K.C., for applicants, stated that in 1900 the Corporation acquired the tramways and got powers to make further lines and to use electric power. The Bill was opposed by his clients on the ground that tramways could not be worked by electricity in the central parts of Manchester without danger to the horse traffic and considerable inconvenience to other traffic. To secure the withdrawal of that opposition it was agreed that the clause on which applicants now relied should be inserted in the Bill. Under that clause the Corporation took powers to make by-laws prescribing the distances that must intervene between tramcars. For two years nothing was done under the section. Then the present applicants moved in the matter, and eventually the Corporation passed a by-law directing that the distances should be as the police regulations provided.

Mr. Justice Channell: Is the point whether the by-law deputing it to the police to say what the distances should be satisfies the clause of the statute?

Mr. Lankester: Yes.

Mr. Justice Channell: I think you can take the rule upon that. I don't express any opinion, but it seems to be a point for discussion.

Electricity Supply and Gas Accounts.

In the Glasgow Sheriff Court last week, Mr. Sheriff Scott Moncrieff was asked by the liquidator of Hutson & Sons (Ltd.) (Mr. J. M. Ross, C.A.) to restrain Glasgow Corporation, whose accounts for gas and electricity supplied to the company's works were admitted to be in arrear, from cutting off the supplies. It was contended that the Corporation, by threatening to cut off supplies, were endeavouring to enforce payment of their accounts and thereby secure an illegal preference, while they were only entitled to rank for their claim as ordinary creditors. The Corporation, by their threatened action would also deprive the liquidator of the supplies of gas and electricity which were necessary for carrying on the company's business, and which he was entitled to get on undertaking to pay for what was consumed subsequent to the date of liquidation.

For the Corporation, it was objected that the application was made in the name of the liquidator and not in that of the company as required by the Companies Acts. It was also denied that the Corporation were seeking a preference. The Corporation were empowered by statute to cut off supplies for overdue accounts and, therefore, were within their rights in exercising their statutory powers.

The Sheriff refused the interdict sought.

Workmen's Compensation.

In the Shoreditch (London) County Court on Tuesday an application was made by Fredk. Statham Sharpe, cable jointer, for a continuance of the payment of compensation by Shoreditch Council. Applicant was injured whilst working at the Council's electricity works in Dec., 1908. He had earned 37s. 6d. a week, and was paid half-wages until April 19, 1910, when the insurance company pleaded that he was cured and declined to pay more. For applicant it was said he tried to work, but had to give it up. It was suggested that the Council should give him a light job.

After hearing evidence, Judge Bray said he thought the insurance company might send him away for a month, and then the Council might try the experiment of giving him light work. The hearing was adjourned for that purpose.

Babcock & Wilcox (Ltd.) v. Edwin Danks & Co. (Oldbury) (Ltd.)

On Wednesday and yesterday (Thursday) Mr. Justice Warrington heard this action, which was brought to restrain defendants from infringing letters patent No. 20,779 of 1898, granted to plaintiffs and Mr. J. H. Harrison for improvements in gas combustion chambers for steam boilers and other furnaces. After hearing evidence, His Lordship came to the conclusion that plaintiffs had failed to establish infringement, and dismissed their action with costs. The defendants' counterclaim, which attacked the validity of the patent, was also dismissed with costs.

Sunderland & District Electric Tramways (Ltd.)—On Friday Mr. Justice Swinfen Eady granted an order to appoint a receiver and manager in a first debenture holder's action. A receiver and manager in respect of a second debenture holder's action had been appointed, and the same gentleman was appointed in the present action.

Postal Telegraph Co. versus Bell Telephone Co. (New Mexico).

From Las Cruces, New Mexico, under date June 25, 1910, we learn that the Postal Telegraph Co. (of New York) has obtained an injunction against a subsidiary Bell Telephone Co. in New Mexico for violation of a contract which the Postal Co. made with an independent telephone company last July for five years by which the Postal Co. reached a number of towns in New Mexico by an extension of its service from El Paso to Silver City, New Mexico. That contract still has more than four years to run. A few weeks ago the New Mexico subsidiary Bell Telephone Co. bought out the independent telephone company with which the Postal Co. had this contract, and then the subsidiary Bell Company notified the Postal Co. that the contract would be repudiated on July 1 and connection cut off. The Postal Co. has obtained an injunction against such repudiation from the district court at Silver City, and has set up that this action is due to a conspiracy between the Western Union and Bell Telephone Companies to suppress telegraphic competition between El Paso, Silver City, and intervening towns and other parts of the country. The validity of the combination of the American Telephone & Telegraph Co. and the Western Union is, we understand, directly attacked by this action.

MUNICIPAL, FOREIGN & GENERAL NOTES.

APPOINTMENTS VACANT AND FILLED.

The Governors of Robert Gordon's Technical College (Aberdeen) are about to appoint an engineer graduate of distinction as head of the engineering department of the college. Salary £500 per annum. Applications to the principal (Mr. Chas. Stewart, M.A.), by July 16.

Applications will be received until Sept. 10 for appointment to the Henry Overton Wills Chair of Physics at Bristol University. Salary £600 per annum. Particulars from the Registrar.

Bombay Corporation require an executive engineer with knowledge of all branches of municipal engineering, including lighting and electricity. Minimum monthly salary R.1,200 (£80), maximum R. 2,000 (£133. 6s. 8d.). Applications to Mr. G. Midgley Taylor, Caxton House, Westminster, S.W., by July 31.

A professor of pure and applied chemistry is required at the Municipal Technical Institute, Belfast. Salary £350, increasing to £400. Particulars from the Principal. Applications by noon July 20.

On Wednesday Salford Corporation appointed Mr. H. J. Hawkins, deputy borough electrical engineer, to the position of borough electrical engineer at a salary of £500, rising by annual increments of £50 to £700 per annum.

Salford Council have also appointed Mr. H. J. Roscoe, of London, superintendent of the hired motor department of the electricity undertaking at £120 per annum.

Mr. C. H. Yeaman, the electrical engineer to the old borough of Hanley, has been appointed electrical engineer to the new county borough of Stoke-on-Trent, which includes Stoke-on-Trent, Hanley, Burslem and Longton. The salary is £500 per annum, with an allowance of £10 per year for local travelling expenses.

Mr. M. W. J. Fry has been appointed Professor of Natural Philosophy at Trinity College, Dublin.

Mr. E. C. C. Baly, F.R.S., Assistant Professor of Chemistry and Lecturer on Spectroscopy at University College, London, has been appointed Grant Professor of Chemistry at the University of Liverpool.

Mr. John D. Coales, D.Sc., A.M.I.E.E., of the Birmingham University, has been appointed principal of the Wolverhampton Technical School.

Mr. A. R. Owen, manager of the Thames steamboat service, has been appointed tramway and mains claims superintendent by London County Council, in succession to the late Mr. J. Glover, at £500 a year.

The First Commissioner of His Majesty's Works has appointed Mr. Howard McFerran to be chief engineer in succession to Mr. E. G. Rivers, I.S.O., resigned.

Mr. G. Bartholomew, charge engineer at Woolwich, has resigned to take up a similar position with the Electric Supply Corpn.

Mr. C. G. Habgood, of Bristol, has been appointed junior engineer at Wednesbury electricity works in place of Mr. Geo. Garratt, resigned.

Mr. E. J. Walsh, of York, has been appointed mains assistant at Leith.

Mr. L. Hulbert, late of the sales department of the Marylebone Borough Council, has taken up an appointment as sales manager to Messrs. Pooley & Austin.

Bermondsey (London) Council has appointed G. H. Endacott (Chingford) arc lamp repairer to the electricity undertaking. There were 122 applications.

EDUCATIONAL NOTICES.

City and Guilds of London Institute.—The entrance examinations of the City and Guilds Central Technical College, Exhibition-road, S.W., and the City and Guilds Technical College, Finsbury, E.C., are held in September, and the sessions commence in October.

Both institutions provide courses of instruction in engineering, chemistry, mechanics and mathematics, &c. Particulars of entrance examinations, scholarships and courses of study may be obtained from the respective colleges or at the head offices of the Institute, Gresham College, Basinghall-street, London, E.C. The Central Technical College is intended for higher technical instruction for day students not under 16 years of age, preparing to become civil, mechanical or electrical engineers, chemical or other manufacturers and teachers. The college is a school of the University of London, and forms the engineering section of the Imperial College of Science. The courses of the study for the associateship of the Institute cover a period of three years.

The City and Guilds Technical College at Finsbury (London, E.C.) is designed for day students preparing to enter engineering and chemical industries and for those who have already served an apprenticeship and also for evening students. The day courses in mechanical or electrical engineering cover two years and those in chemistry three years.

Heriot-Watt College (Edinburgh).—This college provides theoretic a and practical training for mechanical, electrical and mining engineers, technical chemists, brewers, &c., and printers and publishers. The training for engineers consists of three years in the college and a three years' apprenticeship on the "Sandwich" system in a local engineering works. The course in mining extends over two years, and the training is also recognised by the University of London for the B.Sc. degree in mining. Complete courses of instruction, extending over four years, are provided for students studying for the fellowship of the Institute of Chemistry, &c. An entrance bursary of £25 will be offered for competition on Sept. 27 and 28 next. Particulars of fees, &c., may be obtained from the principal, Mr. A. P. Laurie, M.A., D.Sc.

Armstrong College.—Newcastle-on-Tyne Corporation have decided to make an extra grant to this college of £1,500 per annum far five years.

Imperial College of Science.—In December last the London County Council decided to make a maintenance grant of £8,000 to this college in return for the privilege of nominating 25 students for one year's free instruction.

These studentships are now to be filled for the first time, but only advanced students, qualified to enter on the fourth year of the course, should apply. Candidates must be ordinarily resident in the Administrative County of London, and must be students at an institution aided, maintained, or approved by the Council. No examination will be adopted for the final selection of the students from the applications

Digitized by Google

received. The studentships will be awarded on consideration of the past records of the candidates, the recommendations of their teachers, the course of study they intend to follow, and generally upon their fitness for advanced study in science applied to industry. Applications (which will not be considered after July 9) on forms to be obtained from the Education Officer, London County Council, Victoria-embankment, W.C.

BRITISH AND COLONIAL.

Accrington.—The Council are recommended to light Burnley-road electrically from the overhead wires on the tramway route.

Army Pageant Lighting.—During the evening performances the grounds of Fulham Palace (London) were lighted by arc lamps, metal filament lamps and searchlights, as follows:—

Twenty British Westinghouse "Arcturus" flame arcs, 10-ampere size, burning four in series on a 200-volt 50-period a.-c. circuit. Metal filament lamps for lighting the grand stand and two 40-ampere searchlights were used for illuminating the performances.

Australasia.—At the annual meeting of the Electrical Employers' Association of N.S.W., recently, Mr. E. J. Erskine was elected president for the ensuing year. The vice-presidents are Mr. A. J. Hanson and Mr. J. E. Donoghue, and the secretary is Mr. R. Burgin.

The "Australian Mining Standard" says Terang Shire Council have decided to put in additional plant and to substitute incandescent electric lamps for the arc lamps at present used for street lighting.

New plant is being put in at the Golden Horn gold mine, Charters Towers (Queensland), including a Siemens dynamo, driven by a 12½ H.P. gas engine, for lighting the mine.

New apparatus for treatment of slimes at the Cassilis Gold Mine, Gippsland (Victoria) includes electrically-driven centrifugal sand pumps.

Port Pirie (S. Australia) Council have adopted a report by their Lighting committee in favour of electric lighting in the town, and have instructed the committee to appoint an expert to advise them on the subject.

Bispham.—The Council have approved of an electric lighting scheme prepared by Mr. J. W. Speight.

Bray (Ireland).—The electrical engineer (Mr. W. J. U. Sowter) has recommended the Council to adopt the following revised scale of charging for electric current:—

Residences, private hotels, boarding houses, public institutions and churches, hotels open only during the summer months and shops closing at or before 8 p.m. five nights per week, 6d. per unit.

Shops with licensed premises attached and a portion open until 11 p.m. throughout the week, railway and all outside arc lighting where separate meters are fixed, 5d. per unit.

Clubs, licensed hotels open throughout the year, and public houses lighted entirely by electricity, 4½d. per unit.

General flat rate for all other classes 6d. per unit.

Bridlington.—The L.G. Board have sanctioned a loan of £2,975 for the extension of the electricity undertaking, repayable in 17 years.

Buckhaven (N.B.)—Fife Electric Power & Lighting Co. notify that they propose to apply for a provisional order for this district. The Council have decided to oppose.

Carlisle.—An inquiry was held on Wednesday into the application of the Council for sanction to borrow £19,600 for extensions of the electricity undertaking, of which £14,600 was for generating plant, &c., and £5,000 for new cables. The Inspector (Mr. H. Ross Hooper) pointed out, in the course of the proceedings, that the undertaking had no reserve fund, and he strongly urged them to stop paying money to relief of rates until the undertaking had been made financially sound.

Castleford (Yorks.)—The Council have decided to engage an electrical engineer to report on the question of electricity supply.

Customs Duties.—It has been decided that Marconi disc condensers are subject (as electric appliances, n.o.e.) to import duty of 30 per cent. ad val. under the New Zealand General Tariff and to 20 per cent. if of British manufacture.

Under the new customs tariff of the Dominican Republic, promulgated on Jan. 1 last, electrical machinery and apparatus (except lamps and fans) are subject to import duty of 10 per cent. ad. val., instead of the former rate of 73·8 per cent.

Darwen.—The charge for electric current for traction has been fixed at 1½d. per unit, less 2½ per cent.

Derby.—The action brought against the Corporation by Messrs. R. W. Blackwell & Co., the contractors for the local tramways, has been settled by the payment to Messrs. Blackwell of £732. 10s., being half the amount of the penalties deducted by the Corporation, each party defraying its own costs.

Droitwich.—Mr. F. T. Evered, having inquired whether the Council would assent to an application for a provisional electric lighting order, a resolution has been passed to oppose any electric lighting scheme on the ground that it would be detrimental to the gas undertaking.

Electrical Exhibition.—Woolwich Council are desirous of hearing from manufacturers, electrical contractors and others who may be desirous of submitting any electrical apparatus or speciality for exhibition purposes in connection with their central office and showroom which will be opened in a few days. Offers should be addressed to the Borough Electrical Engineer, Town Hall, Woolwich.

Grimsby.—The L.G. Board have sanctioned a loan of £1,420 for providing lampposts, &c., for street lighting.

Hackney (London).—Negotiations are proceeding between the electricity department and Messrs. Lewis Berger & Sons, who already take 300,000 units per annum, and are about to complete the electrification of their factory. They will require about 500,000 units per annum and are disposed to make a three years' contract.

Hampstead (London).—Last week the Council adopted a recommendation of the Lighting committee in favour of lighting the whole of the lamps in the borough (wherever possible) by two 35-watt electric filament lamps at £2. 5s. per annum (and where more powerful lamps are needed at an extra charge of 10s. per annum for each extra 35-watt) until the capital cost of conversion is repaid, and thereafter at £1. 10s. per lamp (with extra for more powerful lamps). The 237 lamps in the Belsize, Fawley-road, Mill-lane and West-end groups of roads are to be converted from gas to electric lighting, each lantern being fitted with two 35-watt lamps, at an estimated cost of £1,580.

Heston and Isleworth.—70 additional gas lamps are to be adapted for electric lighting, and the estimated saving by the conversion is £199. 14s. 10d. per annum.

By increasing the number of 50 c.p. electric street lamps from 226 to 296 the average cost will be reduced from £3. 18s. 7d. to £3, which is within 2s. 11d. of the recently reduced figure for gas lamps averaging 30 to 40 c.p.

After meeting all expenses, excluding any payment for the use of the Baths Hall, there was a net balance of £1. 14s. 6d. on the recent electrical exhibition.

Hull.—The city engineer has been instructed to prepare drawings and specifications for the extension of the Anlaby-road car shed so as to accommodate 24 cars, at a cost of £7,300, and also for the extension of the Hedon-road tramway to the entrance to the new Joint Dock.

Inverkeithing.—The Fife Tramway & Power Co. notify that they intend to apply for a provisional order for this district.

Islington (London).—The Council have adopted the recommendations of the borough electrical engineer (Mr. Gay) as to increasing the capacity of the mains at an estimated cost of £19,872 and also the construction of a new switchboard at a cost of about £3,000.

Leek.—On the recommendation of the Lighting committee it has been decided to increase the price of current for lighting by ½d. per unit on all flat rates, and consumers on the maximum demand system will be charged 7d. per unit for the first hour and 3d. per unit after.

Littleborough.—An unopposed inquiry was held here last week into the Council's application for sanction to borrow £3,500 for the equipment of a transformer sub-station and for laying a distributing network. The Council will take current in bulk from Rochdale Corporation.

L.C.C. Tramways.—On Friday last the running of through cars from Moorgate-street to Whipps Cross, on the border of Epping Forest, was commenced. The fare is 4d.

London County Council.—On Tuesday it was agreed to sanction loans of £10,665 and £5,236 to Hammersmith for electricity purposes.

Ploughs.—It was agreed that the assembling and fitting of the car ploughs required for 40 electric cars should be carried out by direct labour under the management of the Highways committee.

Electricity Meters.—Having considered the draft order proposed to be made by the Board of Trade in pursuance of Sec. 11 of the Electric Lighting Act, 1909, defining the limits of error to be allowed for electricity meters, the Highways committee recommended that no observations be offered on the proposed order.

Maldens and Coombe.—The Council have instructed Messrs. Handcock & Dykes to report on the question of electricity supply in this district.

National Electrical Manufacturers' Association.—The next committee meeting will be held at Balfour House, Finsbury-pavement, E.C., on 12th inst., at 2:30 p.m.

Obituary.—We regret to announce the death of the Hon. Maurice Gifford, C.M.G., of Boothby Hall, Lines., a director of the British Columbia Electric Railway Co. and other public companies.

The death is also announced of Mr. Frederic Nell, a well-known hydraulic engineer, of 46, Queen Victoria-street, London, E.C., and who was associated with many electrical schemes in the early days of the industry.

Digitized by Google

Personal.—On Friday evening last a complimentary bohemian concert was held at Holborn Restaurant to mark the retirement of Mr. Alfred Eames, C.I.S.O., Controller of the Central Telegraph Office at St. Martins-le-Grand, after more than half-a-century's strenuous work. Prior to the concert Mr. and Mrs. Eames held a reception in one of the salons, and many old friends availed themselves of the opportunity to tender them their good wishes.

At the concert Sir Matthew Nathan, G.C.M.G., Secretary to the Post Office, presided, and was supported by several heads of departments, including Mr. A. F. King, second secretary; Mr. A. M. Ogilvie, under-secretary; and Mr. A. G. Leonard, assistant secretary. The Postmaster-General was able to be present for a short period.

Sir MATTHEW NATHAN said it was sad the staff should be losing so sympathetic a chief, the department so able an administrator, and the State so valuable a servant. But it was cause for gladness that on the eve of his retirement he should be singled out for high honour. Mr. Eames had grown up and grown old in the service of electric telegraphy. That practical science came to its majority when Mr. Eames, a boy of 12, joined the Electric Telegraph Co., and in 1870, when the private companies were taken over by the Government Mr. Eames commenced a service which had lasted for 40 years. He began as an operator at the lowest rung of the ladder, and he left it as Controller at the top. The staff under Mr. Eames had increased from 500 to 4,500.

Mr. H. SAMUEL, Postmaster-General, said Mr. Eames was remarkable for the fact that he had risen to a high position in a Government department, although he was born south of the Tweed. He found at the Home Office all the four heads were Scotsmen (laughter). Mr. Eames had watched the growth of telegraphy from its infancy to full development. Mr. Eames had seen vast improvements in the telegraphic service, and in his personal dealings with his staff he had proved that official relations might nevertheless be friendly.

Mr. EAMES briefly returned thanks, and said he would not like to go away without saying how grateful he was for the loyalty and hearty co-operation, and willing assistance which had been given him by everybody.

Presentation.—Bournemouth tramway staff have presented a pair of prismatic binoculars to Mr. F. T. Olding, late traffic superintendent, who is leaving for Queensland.

Salford.—Sub-committees of the Electricity and Tramways committees have arranged that electric current is supplied for traction at the present rate (1.3d. per unit) up to 7,000,000 units per annum; for all units in excess the charge will be 1d. per unit.

School Lighting.—The Education committee of the L.C.C. are to invite tenders for wiring the Sherington-street School, Greenwich.

Shoreditch (London).—The Council have concluded agreements for supplying a number of large consumers with electricity for lighting and power, including Messrs. J. Rotherham & Co. and Messrs. Stollwerck Bros. (for three years), Messrs. Waterlow & Sons (seven years), and the London Theatre of Varieties (five years). In Messrs. Waterlow's agreement a special coal clause is inserted, making the price per unit dependent on the price.

Smoke Abatement.—A deputation from the Smoke Abatement League recently waited upon the President of the Local Government Board (Mr. J. Burns) in regard to enforcing the law as to the smoke nuisance, &c.

In the course of his reply, Mr. BURNS said that he was opposed to the allocation of the profits on gas undertakings in relief of rates, as the effect of that was to make gas dearer than it ought to be, and so prevented its freer use as an illuminant and heater. The contentions of the deputation were that penalties should be increased, that central control and inspection should go hand in hand with local administration, that there should be general, as distinct from local, action both in regard to penalties and standards of smoke, and that there should be national and uniform supervision as against intermittent action on the part of a few public-spirited local authorities. Finally, they asked that areas outside cities should have similar penalties to the cities which they adjoined, so that a man could not get over the border and escape from smoke liabilities and responsibilities. Mr. Burns associated himself with the practical object of the deputation. He believed that much improvement could be accomplished if employers would give practical and technical instruction to their stokers, and afterwards some little encouragement in the shape of extra wages. There were several difficulties to be faced. At present legislation, with the exception of Nottingham, struck only at the factory, the workshop and large undertakings. He agreed that legislation should be made possible in many of the directions they had indicated, but they had not dealt with one of the chief causes of smoke nuisance—namely, the domestic house. In that matter he anticipated more from general progress than from legislation. Great progress had been made in the designing of furnaces, and electric and gas power was gradually taking the place of detached and badly constructed factory boilers and smoky chimneys. All those improvements were a step in the direction of abating the smoke nuisance to which they had not perhaps attached sufficient importance. Whilst there were in Greater London about 35,000 factories and workshops, the dwelling houses numbered 1,000,000. Unless anthracite was insisted upon (which he thought impossible) for every one of those 1,000,000 houses, reform could only be looked for by the education of public opinion. Reform was coming more rapidly than some people thought, in the shape of improved stoves and grates and by the supersession of the coal grate and heater by gas and electricity. He hoped that the day was not far distant when manufacturers would be able to obtain power for their factories and workshops from some central works, where combustion could be much more easily controlled than it now was in the smaller units.

South Africa.—Johannesburg Municipality are in the market for poles, cross-arms and fittings, in connection with electric lighting extensions.

Two large h.-t. generators will be required in connection with the proposed scheme for transferring the Natal Government Railways generating station to Durban municipality.

An electric winder has been ordered from England for the Cinderalla Deep mine.

Southend-on-Sea.—On the recommendation of the Light Railways committee, the Corporation have approved an agreement with the Southend & Colchester Light Railways Co. for an arrangement in regard to the mutual conveyance of passenger and parcels traffic on the light railway between Prittlewell and Victoria Corner and between Prittlewell and Rochford.

Stevenage.—The Council have asked the Board of Trade for a further extension of their 1902 Electric Lighting Order, as negotiations are proceeding with the Electric Supply Corpn. and Messrs. Crompton & Co. with regard to the erection and equipment of electricity works.

Torquay.—The Corporation have adopted a recommendation of the Tramway committee not to consent to the conversion of the local tramways from the surface contact to the overhead system; and in the event of negotiations with the Tramway Co. failing to bring about a satisfactory arrangement the committee have been empowered to refer the matter to arbitration.

Mr. PIKE, chairman of the Tramway committee, stated that they were carrying out the Council's instructions, and were pursuing the negotiations. They did not apprehend that the trams would stop on Oct. 31 next, and he had no doubt that the matter would come out all right.

Warrington.—The salary of the tramways manager (Mr. John Telfer) has been increased to £234 per annum.

Wednesbury.—On Monday the Council approved an agreement for continuing the appointment of Mr. William Fennell, engineer and manager of the electricity works, for three years at £275 for two years and £300 for the third year.

West Hartlepool.—The question of the purchase of certain sections of the Hartlepools tramways by the corporation was again discussed by the Council on Wednesday, when it decided to retain counsel for the arbitration proceedings.

Wigan.—The price of electric energy for traction has been reduced from 1½d. to 1¼d. per unit as from April 1 last.

Winchester.—The City Council, which has decided to purchase the local electricity works, has notified that it will apply for a provisional order to extend the area of supply so as to include the whole of the city, and also certain portions of the rural district of Winchester, including Chilcomb, Easton, Compton, Twyford, Weeke, Littleton, Abbots Barton, Headbourne Worthy, King's Worthy, &c.

Wireless Telegraph Notes.—The installation of wireless telegraphy, which the Spanish Government have organised at the Canary Islands is approaching completion. The Popp system has, it is reported, been adopted, and the radius of communication is claimed to be 3,000 miles. The management of the station at Puntales is in French hands, and it is stated that messages have already been successfully received in Paris from this station.

The Australian Commonwealth authorities are linking up Papua with the mainland by wireless telegraphy. The above connection is in addition to the adoption by the Commonwealth Government of the recommendations of the Conference for linking up the British islands in the Pacific by wireless. High-power stations are to be erected at Sydney, Doubtless Bay (N.Z.), Suva and Ocean Island, and smaller stations in the New Hebrides and the Solomons.

Amongst the important lines of steamships now being equipped with wireless telegraph apparatus are the vessels of the Orient Line, the "Otranto" being the first vessel to be completed

Through the mishap to the "Trieste," concerning whose whereabouts and fate great anxiety was shown over a long period, the attention of several Governments has been directly drawn to the subject of the wireless equipment of all passenger ships. Although the "Trieste" was never off the regular steamer ocean route no word was heard of her from June 14 to July 1.

Wireless Telephone Note.—To the "Glasgow Herald" for Tuesday Mr. C. R. Gibson contributed a popularly-written article on the achievements and prospects of wireless telephony.

Woolwich.—Electric supply mains are to be extended at an estimated cost of £270.

Digitized by Google

ELECTRICITY SUPPLY TABLES AND DATA.

This Valuable Set of Tables and Engineering Data relating to Electricity Supply and to Electric Traction on Railways and Tramways in the United Kingdom, the Colonies, and some important places abroad, is now ready, and can be obtained complete in handy book form, price 6s. 6d. post free, or on very hard paper for rough or constant use, price 8s. 6d. post free. A complete Index is included.

Sports.—The annual athletic sports in aid of the London United Tramways Employés' Philanthropic Fund took place last week at Twickenham. Mr. A. H. Stanley (general manager) was present, and Mrs. Stanley presented the prizes.

The Manchester Corporation Tramway employés sports took place on two evenings last week at Fallowfield. The weather was cold and unsettled.

Annual Outing.—The staff and employés of Tunbridge Wells electricity department had their annual outing last week.

The party travelled by train to Portsmouth and partook of luncheon and tea at the Speedwell Hotel. Mr. J. W. Beauchamp (borough electrical engineer), who occupied the chair, said he regretted that Mr. Boot, consulting electrical engineer to the Corporation, was unable to be present. They were reaping the advantage of the new machinery installed last year under Mr. Boot's supervision. Mr. Beauchamp also spoke of the excellent work carried out by the local wiring contractors, who were represented amongst the guests. He looked forward confidently to the success of the electricity undertaking.

Mr. J. P. STRANGE (for the contractors) said he trusted the good feeling between the electricity department and the contractors would be strengthened in future.

FOREIGN.

Austria.—The Minister of Railways has granted to the Meran and Bozen communal authorities a concession for the construction and working of a light electric railway in Meran.

China.—Consul Goffe (Nanking) writes in his annual report that an electric light company with native capital was formed early in 1909, machinery being obtained from the U.K. It is hoped to commence supply during the current year.

Denmark.—Consul Liddell reports that a scheme is being planned for the construction of an electric railway between Aarhuus and Randers (Jutland) and the supply of electricity in the districts en route. A similar scheme is proposed for the district between Laaland and Falster, with a power station at Maribo.

Patent Law in Holland.—It is announced that the new patent law has been passed by the Second Chamber of the States General and is almost certain to be adopted by the First Chamber within the year. There is a clause for the granting of compulsory licences at the end of three years for patents which have not been worked by the inventors in the kingdom, and another requiring compulsory working either by the patentee or his licensee within five years from the date of grant of the patent.

Portuguese East Africa.—The "British and South African Export Gazette" states that plant and material will shortly be required for a complete telephone service for Lourenço Marques.

Russia.—The Russian Budget for 1910 includes sums of 5,848,000 roubles (£617.289) for construction and repair of telegraph and telephone lines and 65,156,714 roubles (£6,877,653) for extensions of and rolling stock, &c., for State railways.

Consul H. M. Grove (Moscow) states that Saratoff (at which town there is a great demand for electrical material of all sorts) is very largely inhabited by Germans. British firms desiring to do business in Saratoff should write in German, quoting in marks or roubles.

Spain.—The report of Mr. A. Robertson (second secretary to H.M. Embassy at Madrid) for 1909 states that action has been taken in Madrid against commercial travellers for contravening a provision in the Industrial Contribution Law of 1896, that "sellers of articles of novelty of all kinds who keep no open establishment, but receive orders with the right to sell in the whole peninsula," must pay 1,500 pesetas (£55. 11s.) for the privilege.

Imports into Spain for 1909, 1908 and 1907 respectively included the following: Dynamos, electric motors, &c., up to 400 kilos in weight, £113,486, £101,142 and £97,977; from 401 to 2,500 kilos, £149,031, £124,839 and £137,555; from 2,501 to 5,000 kilos, £22,852, £27,311 and £15,094; over 5,000 kilos, £149,031, £127,724 and £64,865. Electric wire over 1 cm. thick, £61,460, £80,433 and £241,812.

Vice-Consul Lovelace (*Dijon*) says the U.K. is holding its own as regards exports of machinery in general to this district, but no headway is being made in electrical machinery and appliances, although these goods are being imported in ever-increasing quantities from Germany.

Vice-Consul Castro (*Corcubion*) says the Brens river supplies sufficient power for the public electric lighting of the towns of Cée and Corcubion, and the acetylene gas works at Brens obtain 6,000 H.P. from the Ezare waterfall, about 6 miles distant.

ELECTRICITY SUPPLY AND TRAMWAY ACCOUNTS.

Bath.—At the meeting of the Council on Tuesday the chairman of the Electric Light committee (Mr. H. T. Hatt) presented the accounts for the past year.

After paying expenses and providing for interest and sinking fund, there was a deficit of £1,400 on the year's working; but, owing to calling upon reserve and suspense funds, the sum recommended to be raised from the next general district rate was only £580. Mr. Hatt said the loss was mainly due to a rapid change over to metal filament lamps. In 1908 they paid off a £30,000 loan, and thus their expenditure and repayment of capital would be £3,000 a year less than now, while the action of the new lamps would prevent the need of increased power to supply additional customers.

Burnley.—Total receipts of the electricity department for the year ended March 31 was £22,998.

Works costs, management expenses, &c., were £11,912. Gross profit was £11,085, and after paying interest on loans (£2,781) and sinking fund (£4,141), and providing for depreciation (£648), &c., there was a surplus of £3,500, which has been applied in relief of rates. £114,000 has been borrowed for the undertaking, and £30,430 paid off, leaving £83,570. Units sold were 3,249,387 (223,395 for power, 749,145 for private and 7,522 for public lighting, and 2,269,325 for traction), against 3,148,875 in 1909; works costs were 0·621d. per unit (against 0·640d.), and the total costs (including interest and sinking fund) 1·392d. (against 1·335d.) There are 998 consumers (against 864), with the equivalent of 72,908 30 watt lamps connected (against 64,692). There are motors of 710¾ B.H.P. connected (against 591 B.H.P.); the load factor was 20·93 per cent. (against 22·75 per cent.), and the maximum load was 2,640 kw., against 1,890 kw. The units sold for lighting increased by 12·77 and for power by 17·54 per cent.; but there was a small decrease (0·81 per cent.) in the traction sales. Lamps connected show an increase of 12·68 per cent. The increase in capital expended was £11,649 (for boiler house plant, a 750 kw. generating set, condensers, &c.).

Chester.—The income from the sale of electricity during the year ended March 31 was £18,212, including £10,021 from private consumers for lighting, £594 for power, £3,867 for public lighting and £2,324 for traction.

Total working expenses were £9,710, leaving gross profit £9,253. Interest came to £3,794 and sinking fund to £3,424. £1,198 was transferred to renewals fund and the balance (£848) placed to reserve. Capital expended is £122,380, an increase of £4,089. 2,293,669 units were generated, 1,010,675 sold to private consumers, 492,296 supplied to public lamps (197 arcs and 719 incandescents) and 366,102 to the tramways department. The maximum supply demanded was 1,400 kw. Works costs per unit sold were 0·658d. (same as in 1909) and total costs 0·935d. (against 0·986d.).

The traffic revenue of the tramways department was £12,038, and the total income £12,464. Working expenses were £7,999. 16s., leaving gross profit £4,464. 10s. 3d. Interest absorbed £2,784, sinking fund £1,018, and the balance (£707) was placed to reserve. Capital expended is £82,785, against £82,813 in 1909. 2,989,706 passengers were carried (against 2,975,590), the car-miles run 346,701 (342,343) and the total number of units used 306,102 (against 335,836).

Glasgow.—The total receipts of the tramways department for the year ended May 31 were £896,720 (against £892,750 in 1908-9), and the traffic receipts were £893,591 (against £889,530).

Working expenses were £502,911 (against £505,617), leaving a balance of £393,809 (against £387,133). Adding interest on surplus revenue account, &c., the gross surplus was £431,549 (£416,924). Deducting rental of Govan and Ibrox tramways (£5,073), proportion of receipts due to Paisley lines (£4,668), interest (£72,289), sinking fund (£85,086), income tax (£15,985), depreciation (£110,688), permanent way renewals (£82,918) and parliamentary expenses (£1,814), the net surplus was £53,028 (against £66,275), which has been transferred to the common good. The average traffic revenue per car-mile has been reduced from 10·262d. to 10·225d. The amounts expended on rates and taxes, third party insurance, permanent way maintenance, and repairs to cars show a decrease of £1,175, £3,385, £1,243 and £3,725 respectively. The balance of tramway debt owing to the Common Good is £2,534,687, and the balance standing at credit of depreciation and permanent way renewals fund is £1,537,641, and at credit of general reserve fund £68,375. The total length of single track is 195 m. 1 fur. and 103 yds. There are 486 top-covered cars, 206 standard cars and 111 converted horse cars, total 803. The car-miles run during the year were 20,974,016, and the number of passengers carried 222,730,571. The percentage of working expenses to receipts was 56·083d. The average working expenses per car-mile (excluding power) was 5·343d., and including power 5·755d.

Hammersmith (London).—The net income from the sale of electric current to private consumers during the year ended March 31 was £44,756. 12s. 3d., and with public lighting revenue (£5,642), meter rent and miscellaneous receipts the total income was £53,433 (against £55,981).

Working expenses were £28,278, and included £14,092 for generation, £2,787 for repairs and maintenance, £3,666 for distribution, £1,407 for public lamp maintenance, £2,593 for management and £2,669 for rates and taxes. Gross profit was £25,155, and after providing for interest (£8,482), redemption of loan capital (£12,491), accruing loan charges, &c.,

Digitized by Google

there was a net profit of £3,483 (against £4,904). The capital outlay is £321,691, an increase of £10,250, but the net debt is only £246,298. 7,054,926 units were sold (against 6,762,861), and the average price obtained was 1·5d. (1·57d.) per unit for public and 1·69d. (1·78d.) for private lighting. There are 2,577 consumers (against 2,336), and there are 385 motors, with the equivalent of 4,587 H.P., connected to the mains, against 339 motors of 2,665 H.P. There are 191 arcs, 63 small arcs and 521 incandescent lamps for public lighting. The maximum supply demanded is 4,653 kw.

The borough accountant (Mr. A. G. Keen), reporting on the accounts, states that the balance of accumulated profit is £850. 18s. 6d., which has been arrived at after writing off amount of loan still unredeemed in respect of plant disposed of (£4,461) and also meeting balance of cost of new turbo-alternator (£2,408), making a total charge against appropriation of profit account for the year of £6,869.

Hull.—The income of the tramways department for the year ended March was £136,985.

Working expenses were £86,098, and after paying interest (£13,776), loan repayment charges (£10,287), contributions towards cost of widening streets (£2,527), and income-tax (£1,355), there was a surplus of £22,942, out of which £16,000 has been voted to relief of rates, leaving £6,942 to be transferred to reserve.

Manchester.—The traffic revenue of the municipal tramways department for the year ended March 31 was £777,219, miscellaneous receipts were £8,546, and parcels revenue £2,264; total £788,029.

Total working expenses were £511,070, including £225,932 for traffic expenses, £74,101 for general expenses, £87,466 for repairs and maintenance and £123,571 for power. Gross profit was £276,959. Interest (£53,500), income tax (£5,661), rent of leased lines (£25,753), &c., were paid, leaving £196,283. Sinking fund (£47,215) and provision for reserve, renewals and depreciation (£70,021) were also met. £75,000 was applied in aid of rates, and the balance (£4,047. 10s. 1d.) in street improvements round the infirmary. The lines open for traffic aggregate nearly 182 miles of single track, of which 876 yds. were opened last year. 159,049,096 passengers were carried, against 155,011,884 in 1908-9, and 17,161,774 car-miles run (17,316,753). Gross capital expenditure is £1,957,594, against £1,837,090.

Newcastle-on-Tyne.—The accounts of the tramways department for the year ended March 31 were approved by the Corporation last week.

The income was £203,339. 4s., but £5,727 had to be paid to the Tyneside Tramways and Tramroads Co., leaving £197,611. 18s. 7d., against £197,885. 4s. 6d. After paying working expenses and providing for interest and sinking fund there was a balance of £15,156 which was carried to reserve and renewals fund.

The chairman of the Tramways committee (Mr. RODGERS), in reviewing the accounts, said that during the nine years the trams had been running they had paid £264,144 off their debt., and had a reserve of £75,272. If they deducted these two sums from the original debt the balance was £836,501.

Oldham.—The report of the borough electrical engineer (Mr. S. Wilmott Newington) states that the capital expended on the electricity undertaking to March 31 was £295,476, an increase of £6,205 during the past year.

The gross revenue was £41,915 and the expenditure £21,772, leaving £20,143 to meet interest (£7,686), sinking fund (£8,237) and interest transferred to sinking fund (£1,824), showing a net profit of £2,203 to be carried forward. 1,859,799 units were sold for lighting and power (against 1,174,067) and the revenue showed an increase of £1,134; 3,860,532 units were sold for traction (against 4,335,972), and the revenue showed a decrease of £3,347. There are 1,226 consumers (against 1,038), and the equivalent of 164,360 8 c.p. lamps is connected (against 146,113). The maximum supply demanded was 1,476 kw. (against 1,363 kw.), and the load factor was 19·68 per cent. (against 21·73 per cent.) Works costs were 0·672d. (against 0·677d.) per unit sold, and the total costs 0·908d. (against 0·910d.).

Sheffield.—The accounts of the electric supply department for the year ended March 25 have been issued and show total receipts from the sale of electricity for lighting power, heating, &c., of £70,641, a decrease of £2,232.

Gross expenditure was £24,354 (against £25,026) and gross profit £51,142 (against £52,702). After providing for interest and sinking fund, &c., there was a deficit of £2,035. There was a drop in receipts for lighting (from £53,117 to £46,265) and there was a decrease of 312,150 in the units sold for lighting owing to increased use of metal filament lamps; but there was an increase of £4,593 in receipts for power (from £18,891 to £23,484), and of £134 for heating.

The chief engineer and manager (Mr. S. E. Fedden) considers that the decrease in the units sold for lighting will probably continue for some time, but as the new connections for the year were 299, against 217 in 1908-9, the department was already beginning to benefit by the reduction in cost to the consumer, and it is expected that the increase in revenue from new connections during next year will counterbalance further reductions from installations changing over to metal filament lamps, so that the lighting revenue during the current year should not be less than this year. The power side of the account was as satisfactory as the light side is the reverse. The figures showed a continuous growth. The power units show an increase of about 1,500,000 over last year's sales, and it is anticipated that there will be a still greater increase during the coming year. Most of the large manufacturing concerns in the city find it to their advantage to take a supply of electrical energy from the Corporation mains. It is also expected that several electric smelting furnaces will be connected during the year, thus largely increasing the power load. The total number of units sold was 10,317,933, compared with 9,029,741. The net decrease in the total revenue was £2,232. Reductions were effected during the year in generation, distribution and management costs. Total costs show a decrease of £672. Total cost per unit was brought down to 0·57d., or 0·09d. less than last year.

TRADE NOTES AND NOTICES.

TENDERS INVITED.

GRIMSBY Corporation invite tenders for supply of 50 c.p. (about) metal filament lamps for 12 months. 300 posts are to be erected. Specifications, &c., from the borough electrical engineer, Mr. W. A. Vignoles, M.I.E.E., Corporation Electricity Works, Grimsby. Tenders by first post July 15. See also an advertisement.

The Lighting committee of DUBLIN Corporation invite tenders for the supply, and the supply and erection of transformers. Specifications, &c., from the city electrical engineer, Mr. Mark Ruddle, Fleet-street, Dublin. Tenders to the Chairman of the Lighting committee, 3, Cork-hill, Dublin, by noon July 16. See also an advertisement.

ST. PANCRAS (London) Borough Council invite tenders for supplying a marine type water-tube boiler, fitted with induced draught. Copies of specification, &c., from the electricity department offices, 57, Pratt-street, Camden Town, N.W. Tenders to the town clerk (Mr. C. H. F. Barrett), Town Hall, Pancras-road, N.W., by 10 a.m. of Monday July 11.

LONDON County Council invite tenders for wiring and fitting for electric light of the second portion of the central car repair depot Woolwich-road, and the supply and delivery of l.t. cables, cable boxes, &c., at the central depot. Specifications, forms, &c., from the Clerk of the Council, Mr. G. L. Gomme, County Hall, Spring Gardens, S.W. Tenders by 11 a.m. of July 12.

LONDON County Council also want tenders by 11 a.m. July 19 for the roadwork and platelaying required for the construction of tramways in Battersea Bridge-road and Beaufort-street, Chelsea, on the underground conduit system, and for paving work. Specifications, &c., from the Chief Engineer, Spring-gardens, S.W.

FLEETWOOD Council require tenders by noon July 15 for supply of a 300 kw. steam dynamo, a l.-t. main switchboard and a 10-ton overhead travelling crane. Specifications, &c., from the Electrical Engineer, Albert-square, Fleetwood.

WALTHAMSTOW Council want tenders by noon July 22 for supply and fixing of a railway weighbridge at the siding adjoining the electricity works. Specification, &c., from the Electrical and Tramways Engineer.

EDINBURGH School Board want tenders by July 12 for the electric lighting of the workshops at the Tynecastle elementary school. Plans may be seen with Mr. Carfrae, 3, Queen-street, Edinburgh.

FULHAM (London) Council want tenders by 4 p.m. July 13 for 12 months' supply of electricity meters. Forms of tender, &c., from the Borough Electrical Engineer, Townmead-road, Fulham, S.W.

WALTHAMSTOW Council want tenders by noon July 22 for supply of car bodies, trucks and electrical and magnetic brake equipments for six double-deck roof-covered tramcars. Specifications, &c., from the Electrical and Tramways Engineer, Priory-avenue, Walthamstow.

WEST HAM Education committee want tenders by 6 p.m. July 18 for electric lighting installation work at West Silvertown school. Specifications, &c., from Mr. Wm. Jacques, 2, Fen-court, E.C.

SWANSEA Harbour Trustees require tenders by 10 a.m. July 15 for three 2-ton electric transporters and overhead travelling cranes. Forms of tender, &c., from the Clerk.

SALFORD Corporation require tenders by noon July 18 for a borehole pumping plant for their electricity works, Pendleton. Particulars from the Borough Electrical Engineer.

MANCHESTER Tramways committee want tenders by 10 a.m. July 19 for supply of h.d. copper trolley wire. Specification, &c., from Mr. J. M. McElroy, 55, Piccadilly, Manchester.

The NEW SOUTH WALES State Railways Department require tenders by July 18 for supply and erection of three 5-ton overhead electric cranes and one 1½-ton and one 1-ton electric travelling crabs. Particulars from the Electrical Engineer, Sydney, N.S.W.

Tenders are invited up to Aug. 2 for the supply and delivery of 1,820 private letter box fronts to the Postmaster-General's Department in the States of VICTORIA, QUEENSLAND, SOUTH AUSTRALIA

Digitized by Google

and WESTERN AUSTRALIA. Tender forms and specifications from the Commonwealth Office, 72, Victoria-street, London, S.W.

Tenders are invited up to July 27 for supply of a pneumatic tube service to the Postmaster-General's Department at ADELAIDE (S. Australia). Tender forms and specifications from the Commonwealth Office, 72, Victoria-street, London, S.W.

Tenders are invited up to July 19 for supply and delivery of 4.200 telephone sets (as per schedule No. 231) to the Postmaster-General's Department in VICTORIA. Tender forms and specifications from the Commonwealth Office, 72, Victoria-street, London, S.W.

The Turkish Ministry of Commerce and Public Works want tenders by Oct. 28 (Nov. 10) for a concession for the construction and working of electric tramways in CONSTANTINOPLE and suburbs. A deposit of £13,500 (sterling) is required with each tender. Local representation is essential. Copy of specification (in French) may be seen at 73, Basinghall-street, London, E.C.

The Société Nationale des Chemins de fer Vicinaux, BRUSSELS, want tenders by July 20 for underground cables, and by July 27 for the equipment of a transformer station.

The Ministerio de Fomento, MADRID, will receive tenders until July 30 for the construction of an electric (or steam) strategic railway from Requena to Alcaráz, via Casas Ibáñez and Albacete. The contract is open to Spanish firms only.

The Ministry of Marine, PARIS, will receive tenders until July 24 for supply of electrical apparatus. Total requirements about £10.000.

COPENHAGEN Corporation require tenders by noon July 16 for supply of three water tube boilers, with superheaters and mechanical stokers, for the Elektrisk station, Gothersgade 30, Copenhagen, where specifications may be obtained.

TENDERS RECEIVED AND ACCEPTED.

Southwark (London) Council received the following tenders for a turbo-generator :—

General Electric Co. (*prov. accepted*), £3,130; C. A. Parsons & Co., £4,265; Willans & Robinson, **£3,601**; Union Electric Co., £1,167 (generator only); Lancashire Dynamo & Motor Co., £1,509 (generator only); Electric Construction Co., £1,087 (generator only); James Howden & Co., £4,412; British Westinghouse Co., £3,170; P. J. Mitchell £3,192; Bellis & Marcom, £3,372; British Electric Plant Co., £3,950; John Musgrave & Sons, £4,498; Brush Co., £3,375; British Thomson-Houston Co., £3,200.

For condensing plant the following tenders were received :—

Worthington Pump Co. (*prov. accepted*), **£1.888**; J. P. Hall & Sons, £1,495 (piping excluded); C. A. Parsons & Co., £1,974; Willans & Robinson, £1,801 (piping excluded); W. H. Allen, Son & Co., £1,721 (piping excluded); Clarke, Chapman & Co., £2,923; British Westinghouse Co., £1,261 (piping excluded); Cole, Marchent & Morley, £1,643 (piping excluded); Bellis & Marcom, £1,809 (piping excluded); United Brassfounders (Ltd.), £1,520 (piping excluded); Ledward & Beckett, £5,267 (evaporative, and cooling tower); Ed. Deane & Beale, £4,504 (evaporative, and cooling tower); Mirrlees-Watson Co., £1,961; Brush Co., £1,755. 10s.; Klein Engineering Co., £1,766 (barometric); Midland Engineering Co., £1,860; and Davenport Engineering Co., £1,650 (barometric).

The following tenders for a cooling tower were also received :—

Davenport Engineering Co. (*prov. accepted*), **£1,327**; W. H. Roy & Co., £1,595; Midland Engineering Co., £1,371; Worthington Pump Co., £1,850; Hudson Economiser Co., £1,417. 5s.; Balcke & Co., £1,581.

Hull Electric Lighting committee have received the following tenders for supply and laying of electric mains, &c., during the year ending March, 1911 :—

Siemens Bros. & Co. (*accepted*)	**£6,772**
Johnson & Phillips	6,866
British Insulated & Helsby Cables	6,876
Callender's Cable & Construction Co.	6,929
W. T. Glover & Co.	6,935
W. T. Henley's Telegraph Works Co.	6,953
Western Electric Co.	6,978
Lahmeyer Electrical Co.	7,181

London County Council have accepted the tender of the Brush Electrical Engineering Co. (lowest tender) for destination indicator boxes for tramcars at £3. 7s. each (total £603). (Five tenders received; highest £5. 12s. 6d. Chief officer's estimate £575. The Brush Co. are to be allowed to sublet the manufacture of the brass furniture to E. Showell & Sons, Ltd.)

Woolwich Council have accepted the tender of Sanders, Rehders & Co. (at £34. 10s.) for a CO_2 "Sarco" recorder for the electricity works, and that of Carter & Wright for a 15 in. centre lathe with accessories for £135.

The "British and South African Export Gazette" states that the General Electric Co. (N.Y.) recently shipped a quantity of switchgear for the Roodepoort United Main Reef Gold Mining Co., which has also purchased 110 motors from the A.E.G. of South Africa (Ltd.).

Liverpool City Council have accepted the tenders of Pulford Bros for upkeep of three sets of accumulators for electric vehicles at £18. 18s. per set per annum, and W. R. Taylor & Co. for oils, paints, &c., for the tramways and electric lighting departments.

Eccles Council have accepted the tender of Stewarts & Lloyds for steel steam pipework at £14. 12s. 6d., and that of H. J. & A. Coulthurst for c.i. condensing water pipework at £25. 10s.

Kingston-on-Thames Council have accepted the tender of Prestwich & Burt for six feeder panels for h.-t. switchboard and other work, at a cost of £334. 19s.

Staffordshire Education committee have accepted the tender of the Walsall Electrical Co. for wiring the Dorsett-road schools, Darlaston.

Margate Council have accepted the tender of the Jandus Arc Lamp Co. for five arc lamps at £6. 16s. each, and that of Kingston & Co. for wiring the Westbrook Pavilion at £43.

Manchester Tramways committee have accepted the tender of the Lorain Steel Co. (Johnstown, U.S.A.) for the supply of special track work.

Southend Light Railways committee have accepted a quotation of the Jandus Arc Lamp Co. for supply of nine enclosed flame arcs for £73.

Wrexham Council have accepted the tender of the British Insulated & Helsby Cables for the supply of electric cables.

Derby Corporation have accepted the tender of W. H. Keys (Ltd.) for 20 tons of bitumen.

Salford Council have accepted the tender of P. R. Jackson & Co. (at £39. 15s.) for a spare armature.

Rochdale Council have accepted the tender of Whipp & Bourne for boosters, &c.

Leyton Council has accepted the tender of Fraser & Fraser (at £70. 10s.) for an ash elevator for the generating station.

Accrington Council have placed an order with the Brush Co. for two double-deck tramcars at £740 each.

Stoke-on-Trent Council have placed an order with the British Westinghouse Co. for six 30 kw. transformers at £44. 10s. each.

Bridlington Council have accepted the tender of Waring & Gillow for illuminations on the Royal Prince's Parade at £200.

BUSINESS NOTICES.

Mr. John Wood, junr., has been admitted a partner in the firm of Mosses & Mitchell. The style of the firm remains unchanged.

Brook Shaw and Ernest H. Pickford (trading as Brook, Shaw & Co.), mechanical and electrical engineers, 264-266, Ecclesall-road, Sheffield, have dissolved partnership. Debts by Mr. Pickford.

The Asbestos & Engineers' Stores Co., 56, Bermondsey-street, S.E., announce that they have secured the services of Mr. Wm. Deller.

The partnership between J. H. and W. G. Stones, engineers and patent agents, 10, Richmond-terrace, Blackburn, carried on under the style of Stones & Stones, has been dissolved. Debts by Mr. J. H. Stones.

Sale by Auction.—Mr. W. H. Robinson will sell by auction at the Albion Hotel, Piccadilly, Manchester, on Tuesday, July 19, at 5 p.m., a plot of freehold land, containing about 5,089 sq. yds., together with substantially built premises recently occupied by Messrs. W. Brown & Sons (contractors and builders, Salford) and their subtenants. The purchaser will have the option of buying the machinery, plant and fixtures on the premises within seven days from date of sale. The land and premises are conveniently situated, and are opposite to the principal entrance of and in close proximity to the most central portion of the Manchester Ship Canal and its docks. Further particulars from the Auctioneer, Cromwell-buildings, Blackfriars-street; from Messrs. Charles Dunderdale & Co., solicitors, Marsden-street; or Messrs. March, Clayton & Pearson, 22, Bath-street, Manchester. See also an advertisement.

Patent Development.—The proprietor of British patents Nos. 14,304 1899 and 16,489/1902, relating to "Improvements in and the Application of Electric Motors for Automobile Vehicles," desires to enter into arrangements for developing and working same in this country. Applications to Messrs. W. P. Thompson, & Co. 285, High Holborn, London, W.C.

Agent Wanted.—A German firm manufacturing watertight electrical appliances requires an agent to sell goods on commission.

"A.E.G. Bulletin."—The July issue of this Bulletin is of interest mainly on account of its articles on the A.E.G. steam turbine. This

Digitized by Google

is written by H. Treitel, and contains a number of efficient diagrams. The Bulletin also includes a description of the lighting of the Kaiser Hof at the Brussels Exhibition.

Small Motors and Vacuum Cleaners.—A small dynamo and motor list is being issued by the Eclipse Electric Co., St. John's-road, Bootle. The dynamos have been built specially for direct coupling to petrol and paraffin engines. The prices of these machines are extremely moderate. The same firm send us details of a motor-driven vacuum cleaner, illustrated herewith, which is suitable for use in hotels, large private houses, flats, public buildings, &c. The double bellows are operated by a connecting rod from a large pulley which is belted up to the motor. The latter develops ¼ H.P. and is compound wound. The motor is protected by a d.p. fuse and a

tumbler switch only is used for starting. The entire outfit is mounted on wheels and with each machine a number of suction nozzles are provided.

CATALOGUES, &c.

Conduit Wiring.—We have received a copy of the third edition of Conduit Wiring, by L. M. Waterhouse, managing director of Simplex Conduits (Ltd.). We understand that this edition brings the total number published of this useful book to 20,000 copies. The present volume contains a number of useful additions, particularly on lamps and illumination, electric ventilation, breakdown of cables, &c. The book is a very complete exposition of Simplex conduit wiring practice.

Waterproof Switch Boxes.—Messrs. Siemens Bros. Dynamo Works are publishing a pamphlet which gives the prices and general particulars of their weatherproof switchboxes and ironclad motor control panels. These are all of the weather-proof type, and are fitted with the latest pattern of "Zed" fuses.

Precision Instruments.—A catalogue of testing instruments, which deals with precision type wattmeters and current and pressure transformers, has been published by Messrs. Siemens Bros. & Co. The instruments are listed with pivoted and suspended movements, both of these being in two types. The current and pressure transformers are quite portable and are guaranteed of high efficiency.

G.E.C. Publications.—From the General Electric Co. we have received a copy of the G.E.C. progress sheet and pamphlets dealing with Osram lamps, cast-iron wall plugs and measuring instruments. Included in the progress sheet is a line of G.E.C. electrically-driven portable vacuum cleaners. Considerable space is also given to Aron motor meters. From the same quarter also we have received copies of a booklet describing portable battery-driven electric fans and the fold-easy telephone bracket. The latter is an extremely convenient device which can be adapted either to the wall, desk or table.

Osram Lamps.—At the recent fancy dress roller skating carnival at Long Eaton, Mr. A. Burns, a local electrician, obtained first prize for the most original costume representing a well-known advertisement. Mr. Burns selected a number of Osram window and show cards and illuminated these with small battery Osram lamps. He also attached coloured Osram lamps to each shoulder, one on each sleeve and one on each leg, while his head dress comprised a peaked cap shaped to represent an Osram lamp. Two 20 ampere-hour accumulators used alternately and strapped on the shoulder supplied the necessary energy.

BANKRUPTCIES, LIQUIDATIONS, &c.

At Liverpool Bankruptcy Court on Friday an application was made to Judge Thomas to grant the discharge of Alfred Horswill Gibbings, electrical engineer.

The Deputy Official Receiver (Mr. T. W. J. Britten) reported that the receiving order was made against debtor in March, and his statement of affairs disclosed liabilities £2,783, and assets (chiefly furniture) £59. The assets produced only £14. After paying a preferential claim there was a balance of £12 for costs, and that amount was insufficient by £15 to cover. No dividend could be paid to unsecured creditors. Debtor had held various appointments as electrical engineer. In 1908 he entered into an agreement to act as consulting engineer to the North British Electrical Power Synd., which completed a scheme of supplying electrical energy at cheap rates by utilising way leaves along railway lines. The scheme was spoilt (according to debtor) by the insertion of a clause in the Electric Lighting Act, 1909, prohibiting a private company from supplying electrical energy in competition with a local authority (or other statutory undertaker) without a provisional order. The syndicate was dissolved, and to that the debtor attributed his insolvency.

On behalf of debtor Mr. Cuthbert Smith said the £250,000 capital needed for the electric supply scheme had been secured. But for the clause referred to that undertaking would have been carried out, and Mr. Gibbings would have realised £15,000 in fees alone and a large permanent income. Most of his debts had been incurred in conducting the negotiations and securing wayleaves for the scheme. The creditors were mostly makers of electrical plant, who were to benefit from the scheme, and had advanced money to him after he had fully disclosed to them his financial position. No creditor opposed his discharge. He was now in employment, earning £4 a week, and in view of the special circumstances he asked for his discharge, offering to find £55 to pay off all the purely domestic debts.

His Honour said the bankruptcy was of an unusual character. He was satisfied most of debtor's liabilities were incurred in the way referred to by him and with the knowledge and willing assent of all the parties concerned. The case, therefore, came very near one that was due to circumstances beyond debtor's control. He thought justice would be met by granting the discharge, subject to consent to judgment against the debtor for £150 and the £15 due for costs, execution not to be levied without leave of the Court. To this course debtor consented.

On Friday the public examination was concluded of E. W. J. Peterson, solicitor, 59, Lincoln's-inn-fields, W.C. whose accounts show a deficiency of £1,549.

Debtor stated that for the past 10 years he had devoted his time to the promotion of light railways and similar undertakings in various parts of England.

A receiving order has been made against Frank Sheppard, electrician, 4, Haslett-road, Kensington, London. First meeting of creditors July 14 and public examination on Aug. 16, both at Bankruptcy-buildings, London, W.C.

An application for the discharge of Alfd. Jas. Hollington, electrical engineer, formerly of Hermon-hill, Wanstead, and 37, Walbrook, London, E.C., will be heard on July 21 at Bankruptcy-buildings, London, W.C.

Mr. Harry Wilson, 23, Devereux-court, Strand, London, W.C., has been appointed trustee in the bankruptcy of John L. P. Donlevy, consulting electrician, 123, Tulse-hill, London, S.W.

PATENT RECORD.

APPLICATIONS FOR PATENTS.

*Note.—The undermentioned Applications (except those marked †) are not open to public inspection until after acceptance of Complete Specifications. Those marked * are open for inspection 12 months after the date attached to them, if they have not been published previously in the ordinary course. COMPANIES' MEETINGS AND REPORTS.

Electric & General Investment Co. (Ltd.)

The twenty-first ordinary general meeting of the company was held yesterday (Thursday), Mr. J. B. BRAITHWAITE presiding.

The SECRETARY (Mr. S. R. Shaw) read the notice convening the meeting and the auditors' report.

The CHAIRMAN said: I think we may be fairly well satisfied with our position. Last year showed an improvement, as you will remember, of roughly, £4,000 on the previous year, and this year shows a further improvement on last year of £1,500, and it is that extra amount which we are proposing to distribute as dividend. Last year we placed the whole of the surplus to the contingency fund, and this year we are putting £4,296. 7s. 1d. to the fund, against £4,098. 8s. 7d. last year, which raises it to a figure close on £76,000. We are distributing 6 per cent. on our ordinary shares, and as trustee for the reserve fund I am distributing 2½ per cent. from that fund on the ordinary shares, so that our shareholders this year will get 8½ per cent. upon their investment, which, I think, in view of all the circumstances, is not unsatisfactory. Turning to the balance-sheet, you will there find that the position has distinctly improved during the period under review. The capital, of course, is unchanged, but whereas last year we had loans from bankers of £67,800, this year that item is reduced to £48,000, which shows that we have paid off close on £20,000 during the year. On the other side, the item of loans against securities has increased from £16,890. 19s. 2d. to £19,513. 8s. 6d., so that we have nearly a further £3,000 there to our credit. Sundry creditors and open accounts at the close of the financial year had increased from £14,474. 10s. 2d. to £22,899. 13s. 4d. That was due to engagements for the settlement on the Stock Exchange in the middle of June. The net result of the year's operations is that we have a profit of £13,088. 19s. 6d. After paying our preference dividend, which absorbs £5,970, the same as last year, and placing £4,296. 7s. 1d. to the contingencies fund, we have a balance of £1,200, which is equal to 6 per cent. on the paid-up ordinary capital. I have had a letter from one shareholder inquiring how it is that we are only distributing a quarter of our surplus profits. Well, I do not think I need say very much on that point, because, as you are aware, we have been steadily building up the contingencies fund to counter-balance in some sort the depreciation shown by many of the securities we hold. This company is largely interested in the British Electric Traction Co., whose securities show a very large depreciaton, a depreciation which, I hope, will gradually be recovered, but at the moment I think we are wise in steadily adding to the provision for contingencies by strengthening the position of the company. (Hear, hear.) If our hopes should be realised, and the British Electric Traction Co. should recover something of its old prosperity, that money will be available for distribution between the ordinary and the founders'shares. Respecting the British Electric Traction Co., no doubt some of you have observed the steady improvement which is going on in the position of that concern. Those of you who have studied its balance-sheet will have noticed the distinct strengthening of the position which it shows. That the traffic receipts are showing such improvement all along the line is very encouraging for the future. The Metropolitan Electric Tramways Co. is showing an increase of a considerable amount, and if one looks down the list of the Traction Company's undertakings in all parts of the country one sees that in almost every case an improvement is going on. In some directions it has reached a very substantial figure. Our investments have appreciated £10,000 as compared with the previous year; we have repaid £20,000 to our bankers, which is satisfactory; and we have earned you a little more profit, which enables us to make an increased distribution. I now move the adoption of the report and accounts.

Mr. EMILE GARCKE seconded the resolution, and added that, with regard to the British Electric Traction Co., he did not wish in any way to minimise what Mr. Braithwaite had said.

The resolution was carried unanimously.

Motions for the approval of the dividends set out in the report, for the re-election of the retiring director (Mr. J. Cecil Bull) and the retiring auditor, were afterwards submitted and approved, and the proceedings terminated.

J. G. White & Co. (Ltd.)

At the meeting last week the CHAIRMAN (Mr. J. G. White) said that the past year's profits amounted to £64,801, against £39,977 for 1908-9, which, in turn, were slightly larger than for any former year. The securities now owned had a total par value of more than £650,000. There had been considerable sales at profitable prices of investments formerly held. The directors considered the investments were valued on an extremely conservative basis. The item "Plant and stocks of material," at £2,645, was unquestionably valued conservatively. Everything was appraised on practically scrap value basis, and the figure by no means represented the working value of the plant and materials to the company in its current business. "Purchase of business" stood at the original figure, £47,975. A considerable item was set down in the balance-sheet as "Percentage due to directors and staff." He did not himself participate in the distribution of this item, and could speak quite freely about it. It was considered that the interests of the company were materially promoted by having a substantial portion of the remuneration of the heads of departments in the business, and of those directors who were also members of the staff and who devoted their time exclusively to the company's affairs, contingent on the profits shown by the company. It obviated the necessity of the actual salary list being unduly high, so that should the company have a period of reduced business and be forced to economise, payments to the more highly paid members of its staff would be automatically reduced without requiring a reduction in salaries or of staff. In a company such as theirs good organisation was one of its greatest assets. Remuneration being contingent on profits of the company harmonised the interests of the staff and of the company, gave additional incentive to hard and earnest work, and contributed to greater general efficiency. After allowing for £15,460 brought forward, and for interim preference dividend and the percentage to staff (£7,882), there remained £67,879 to be dealt with. The profit for the year was the largest by more than 50 per cent. in any year in the company's history. It was now 10 years since their company was formed, and its growth had, on the whole, been continuous and regular, largely, they believed, due to the conservative policy which had been adopted in accumulating reserves. A reserve fund of £100,000 had been created, and there remained a balance of £52,379. The directors felt justified in recommending a dividend at the rate of 10 per cent. on both classes of their shares, which, it was hoped, would not by any means mark the maximum warranted distribution to shareholders. The directors believed that the true present value of the goodwill of the company was very much larger than the figures shown in the balance-sheet. Yet, as that was the only item on the credit side of the balance-sheet which was intangible, it was believed that it would be advantageous to wipe it out as rapidly as might be done, before any further additions were made to reserve or dividends further increased. Therefore it was recommended that out of the balance £32,975 be written off "Purchase of business," leaving it at £15,000, and that £19,404 be carried forward. The directors looked forward with confidence to the future.

The report and accounts were adopted.

EDMUNDSON'S ELECTRICITY CORPN. (LTD.)—The directors' report for the year ended March 31 states that the net profit, after payment of debenture interest amounts to £10,768 (with £14,809 brought forward £25,577), which the directors recommend be carried forward. The dividends and interest received have increased by £5,128, whilst the loss on working the local authorities' undertakings is reduced by £722 and the Urban Electric Supply Co. guarantee is £2,505 less. During the year notice was received from Winchester Corporation of their intention to purchase the Winchester electricity undertaking.

ELECTRIC CONSTRUCTION CO. (LTD.)—The net profit for the year ended May 31, after payment of £9,425 for debenture interest and crediting £5,000 as formerly to depreciation account, is £7,123. 5s. With the amount brought forward (£3,687. 16s. 8d.) the sum available for dividend is £10,811. 1s. 8d. The dividend on the 7 per cent. cumulative preference shares requires £4,394. 12s., leaving £6,416. 9s. 8d. to be carried forward. The directors regret the results for the past year do not entirely fulfil the hopes expressed in their last report. Few orders, however, for large installations have been placed, and consequently the works have not been fully employed. The reduction in gross profit is due to the diminution in the volume of business, but the directors hope that the recent improvement in trade may lead to an increased demand for electrical machinery. Meanwhile, the closest attention continues to be paid to costs of production, and a further reduction in expenses has been effected. The directors have availed themselves of an opportunity of redeeming part of the second mortgage debenture stock on favourable terms, and the amount outstanding has been reduced to £10,000. A considerable saving in interest will thus be effected.

ELECTRIC TRACTION CO. OF HONG KONG (LTD.)—At the meeting on Wednesday the report and accounts (abstracted in our last issue) were adopted. Resolutions were also passed authorising the extension of the borrowing powers, the alteration of the name of the company to the Hong Kong Tramway Co. (Ltd.), and the reduction of the capital of the company to £81,250.

GREENWOOD & BATLEY (LTD.)—At the meeting on Saturday the chairman (Major-Gen. Micklem) expressed regret at the death of Mr. Arthur Greenwood, who had been chairman of the company since its formation. The machinery department had been busy during the year, and the electrical department fairly well employed, but in face of severe competition only a bare margin of profit had been gained. Employers' liability insurance last year cost £576, and rates and taxes £2,594, which together equalled a dividend of 1½ per cent. on the ordinary shares.

Digitized by Google

KALGOORLIE ELECTRIC TRAMWAYS (LTD.)—At the meeting on Tuesday the chairman (Mr. A. H. P. Stoneham) said that the gross receipts showed a decrease of £2,100 compared with those for 1908, but the net profit was larger by £1,170. The falling off in receipts was mainly due to depression in the mining industry.

NATIONAL TELEPHONE CO. (LTD.)—The directors have decided, subject to audit, to recommend at the forthcoming meeting of shareholders, the following dividends for the half-year ended June 30, after payment of the dividends on the preference shares: At rate of 6 per cent. per annum on the preferred and deferred stock (less tax), carrying £175,000 to reserve and about £15,000 forward. The transfer books will be closed from the 15th to the 28th inst. inclusive.

NORTH STAFFORDSHIRE TRAMWAYS CO. (LTD.)—At the meeting last week the chairman (Mr. W. C. Bond) said that their liability to the Potteries & District Electric Traction Co. had been reduced to £32,329. The expenditure on capital account during 1909 was £348. After including amount payable by the Potteries Co. and deducting debenture interest the balance profit was £4,958, or including balance forward £6,055. Five per cent. was declared on the ordinary shares, and £1,255 carried forward.

PERTH (W. AUSTRALIA) ELECTRIC TRAMWAYS (LTD.)—The chairman (Mr. A. H. P. Stoneham) on Tuesday reviewed the history of the company. In 1898, when the company was formed, the people of Perth did not subscribe for a single share or debenture, but were now casting longing eyes on the property and openly saying that the tramways should be their property, and, moreover, seemed to think that it should be sold to them at less than cost price, just as they were about to get the reward to which they were entitled for the risks they had run and the enterprise they had shown. The original concession was for 17 miles of track, but in order to meet the convenience of the people they were now operating nearly 30 miles. They were still being asked to build more extensions, and the board requested Mr. Wren to go out to meet the Council and explain to them that they were willing to do anything in reason to meet the convenience of the citizens, provided they on their side were willing to give reasonable facilities for obtaining fair interest and fair security for the money. Mr. Wren found the Council unwilling or unable to make any such arrangements. The company was a commercial concern, and had made a success of their undertaking, and were anticipating the reward of their past efforts. The company had received information that the Council would prefer to buy the company out, and a reply had been sent, stating that if a satisfactory offer were received it would be submitted to the shareholders. They had received an offer which they did not consider satisfactory. The board's view was that if bought, they should be acquired by the State and not by the Town Council. The State of New South Wales bought the Sydney tramways and had made them a great success. The accounts showed considerable improvement upon those of the last three years. For the first six months of this year the traffics were £3,360 in excess of those of last year, and so far as the board could judge the profits were nearly £2,200 in excess.

VICTORIA FALLS & TRANSVAAL POWER CO. (LTD.)—The directors' report for 1909 states that the past year has again been mainly occupied by construction work. The surplus for the year (£50,534), added to that brought forward (£84,863), makes £135,397. In consequence of the unexpectedly large and increasing demand of consumers, necessitating further capital expenditure, which ultimately will be met by increasing the debenture debt, the directors have carried this amount forward, and therefore no distribution of dividend on the preference shares will be made for 1909 before May next, when the new station at Rosherville will be in full operation.

NEW COMPANIES, MORTGAGES AND CHARGES.

NEW COMPANIES.

ACTON LAMP CO. (LTD.) (110,486.)—Reg. June 30, capital £8,000 in £1 shares, to carry on the business of manufacturers of and dealers in electric glow lamps and other electric lamps, &c. Private company.

EAST KENT ELECTRIC SUPPLY CO. (LTD.) (110,494.)—Reg. June 30, capital £30,000 in £5 shares (1,500 preference), to carry on the business of electrical engineers, electricians, practical engineers and contractors, manufacturers of and dealers in electrical apparatus, suppliers of electricity, &c. First directors, G. Holman, S. W. Price and H. F. Holman. Reg. office, 36-8, New-street, Ashford, Kent.

ELECTRO-METALS (LTD.) (110,432.)—Reg. June 28, capital £30,000 in 4,000 preference shares of £5 each and 10,000 ordinary shares of £1 each, to carry on the business of engineers, electricians, metallurgists, miners, contractors, merchants, &c., and to adopt an agreement with Jens Orten-Boving, D. Spencer, and P. R. Cobb (trading as Jens Orten-Boving & Co.) Private company.

INTERNATIONAL "Z" ELECTRIC LAMP ASSOCIATION (LTD.) (110,468.) Reg. June 29, capital £40,000 in £5 shares (4,000 preference), to carry on business as manufacturers of incandescent lamps and other electrical apparatus, fittings and plant, electricians, electrical engineers, &c., and to adopt agreements with the Compagnie Internationale des Lamps Electriques Zircone Wolfram (Soc. Anon.), with the "Z" Electric Lamp Mfg. Co. (Ltd.) and with Kilburn, Brown & Co. First directors, A. Simson, A. Romberg and W. L. Pakenham. Reg. office, Orient House, New Broad-street, London, E.C.

OUDTSHOORN ELECTRIC LIGHT & POWER CO. (LTD.) (110,512.)—Reg. June 30, capital £15,000 in £5 shares, to carry on the business of suppliers of electricity, engineers, &c., and to acquire from the General Electric Co. (Ltd.) the concession granted by the Municipal Council of Oudtshoorn, Cape Colony. Private company. First directors, H. Hirst, G. T. Moody, H. Kahn and A. I. S. Baron. Reg. office, 71, Queen Victoria-street, London, E.C.

UITENHAGE ELECTRIC LIGHT & POWER CO. (LTD.) (110,452.)—Reg. June 28, capital £15,000 in £5 shares, to take over from the General Electric Co. (Ltd.) a concession granted by the Municipal Council of Uitenhage, Cape Colony, for the lighting of the town by electricity and the supply of electrical energy to private consumers. Private company. First directors, H. Hirst, G. T. Moody, H. Kahn and A. I. S. Baron. Reg. office, 71, Queen Victoria-street, London, E.C.

MORTGAGES AND CHARGES.

CASCADE (1906) POWER CO. (LTD.)—A memorandum of satisfaction to the further extent of £43,417 on various dates from February 4 to May 24, 1910, of trust deed dated Sept. 21, 1906, securing £75,000, has been filed.

ELECTRIC LIGHT, POWER & HIRING CO. (LTD.)—A memorandum of satisfaction on June 15 of mortgage dated Feb. 22, 1909, securing all moneys due or to become due from company to bankers up to £9,507.3s.11d. has been filed.

NOTTINGHAMSHIRE & DERBYSHIRE TRAMWAYS DEVELOPMENT CO. (LTD.)—Particulars of £5,000 debentures, created June 22, 1910, have been filed, amount of present issue being £500. Property charged: Company's undertaking and property, present and future, subject to prior charge. No trustees.

PEARSON FIRE ALARM (LTD)—Mortgage dated June 15 (supplemental to trust deed dated March 2, 1908, securing £20,000) charged on certain patents and trade marks. Trustees, T. D. Cocke and A. Hair.

CITY NOTES.

MEMORANDA (July 7).—Bank rate 3 per cent. (since June 9, 1910). Price of silver, 24 1/16d. per oz Consols 81 7/8—82 1/8 for money; 82—82 1/4 for account. **Consols Pay Day, Aug. 4; Stock and Shares Continuation Days, July 12 and 26; Ticket Days, July 13 and 27; Pay Days, July 14 and 28; Mining Shares Carry Over Day, July 11.**

PRICES OF METALS (London).—*Copper*, cash, 54 3/8; three months 55 1/16. *Lead*, English, 12 3/4—13; foreign, 12 5/8. *Spelter*, 22 5/8—22 3/4 *Tin*, English, 148—150; foreign cash, 149 1/2; three months, 150 1/4 *Iron*, Cleveland, cash, 48/10, three months, 49/7.

CAVEHILL & WHITEWELL TRAMWAYS CO.—A resolution has been agreed approving the Bill of Belfast Corporation for the purchase of the company's undertaking.

DUBLIN UNITED TRAMWAYS (1896) (LTD.)—The directors have declared a dividend for the half-year to June 30 at the rate of 6 per cent. per annum, less tax, on the preference and ordinary shares, after setting aside £4,000 for renewal of cars and carrying forward £7,291.

EASTERN EXTENSION, AUSTRALASIA & CHINA TELEGRAPH CO. (LTD.) Interest on this company's 4 per cent. mortgage debenture stock for the half-year ending July 31 will be paid by warrant on Aug. 1. The stock register will be closed from 27th to 30th inst. inclusive.

MEXICO TRAMWAYS CO.—The directors have declared a dividend of 1 1/4 per cent. for the quarter ended June 30.

NATIONAL TELEPHONE STOCK.—It is not surprising that as the time draws nearer for the transfer of the National Co.'s business to the State, speculation is rife as to the proportional distribution of the company's liquid assets over the various denominations of stocks and shares into which the capital of the company is divided. A lengthy review of the position was given in the "Financier" for July 1. In this review it is well stated that "When the time arrives for arbitration as between the Post Office and the company, the scales of justice should be held as even as human judgment can arrive at, but where any doubts may arise that cannot be quite clearly dissipated, the company rather than the Government should have the benefit." In the "Financier's" review this is intended to apply to shareholders' interests; it applies with added force to the interests of the company's staff.

NORTHAMPTON ELECTRIC LIGHT & POWER CO. (LTD.)—A circular has been issued to the shareholders stating that the debentures are to be redeemed on Jan. 1 next at par, and the directors have resolved to issue their 4 per cent. debenture stock, which is at present limited to £50,000.

RIVER PLATE ELECTRICITY CO. (LTD.)—Notices are being issued to the shareholders as to the conversion of 120,000 £1 ordinary shares into £120,000 ordinary stock, and of 100,000 £1 preference shares into £100,000 6 per cent. non-cumulative preference stock.

ROYCE (LTD.)—It is announced that the dividend on the preference shares will be passed.

STOCK EXCHANGE NOTICES.—The Stock Exchange committee have granted quotations to 99,400 £1 fully-paid shares of the *Llandudno & Colwyn Bay Electric Railway (Ltd.)*, 600,000 £1 fully-paid ordinary shares of *Mather & Platt (Ltd.)* and a further issue of £35,326 4 1/2 per cent. first mortgage debenture stock of the *Rangoon Electric Tramway & Supply Co. (Ltd.)*

TRAMWAYS & LIGHT RAILWAYS ESTATES CO. (LTD.)—The accounts for 1909 show a net profit of £527. A dividend of 2 1/2 per cent. is recommended.

NOTES.

The Portability of Standard Cells.

IT has always been a marked feature of the standard cell, as developed during the last 20 years, that it should be portable. Ordinary portability—by which we mean the character that enables the cell to be carried readily from one establishment to another with a little care—is easily secured, but it is generally desirable to go a stage further than this and to secure what may be termed "universal portability." By this we mean a construction enabling the cell to be posted from one part of the globe to another without ill effects, even though it may have been inverted for a considerable part of its journey. Many methods have been proposed to attain this end. Thus, in the old test tube form of cell the platinum was frequently amalgamated and the cell was well packed up with crystals so that there was not anything tending to shift to any great extent. Again, crystal cells, that is, cells made up of damp crystals without any otherwise free solution, were proposed many years ago by Profs. CALLENDAR and BARNES. In the H form of cell the problem is not quite so easy, and it has been customary, as recommended by the National Physical Laboratory, to form a crystalline plug in each leg of the cell below a constriction in the glass tube. This device seems to act satisfactorily, but such crystalline plugs are liable to increase the internal resistance of the cell, and although the E.M.F. is unaffected, a cell with a very high internal resistance is by no means so convenient for laboratory measurements as one with a low internal resistance, while in some cases its use becomes comparatively limited. The modification introduced by Mr. H. TINSLEY, which our readers will find described in another column, seems to be an effective way of getting over the difficulty. Mr. TINSLEY simply uses small perforated corks on to which a disc of linen is sewn, and this is forced down on the top of the crystalline materials. With suitable precautions such a method should give no trouble; there should be no increase of resistance, and it should prove an effectual barrier to any displacement of the ingredients.

Electricity Supply in the Potteries.

IT is not so long ago since we drew attention to proposals that were being made to combine the five pottery towns in North Staffordshire into one county borough. At that time we welcomed the idea and pointed out the advantages which would result from this co-operation. This combination has now been accomplished and among the first steps that have been taken is one towards the unification of the electricity supply, Mr. C. H. YEAMAN, of Hanley, having been appointed to undertake this by no means easy task. Unfortunately the inhabitants of these islands are essentially parochial. They consider simply their own immediate neighbourhoods and their view is correspondingly narrow. When railways first came into general use, lines were laid down in practically the same area with entirely different gauges so that intercommunication was impossible, and even now we see two adjacent tramway undertakings working with different gauges and sometimes on different systems.

THIS lack of foresight will now cause Mr. YEAMAN some trouble in the new borough of Stoke-on-Trent. The borough already possesses four electricity stations, three of which supply continuous current on the three-wire system, and the fourth single-phase alternating current with a frequency of 100. As the alternating current area is right in the middle of the others, it is hard to see how it can be ignored, or this might otherwise have been the easiest solution. The worst of it is that this is the sort of mistake that might have been avoided. The authorities who were responsible for the introduction of electricity supply into these districts might, had they been less self-centred, consulted as to what common method they

Digitized by Google

should use. They might have foreseen that a time would come when it would be convenient to combine, and that a variety of systems would not help towards this end. They might even have erected one station to supply the whole of the area involved. But they did none of these things, and Mr. YEAMAN will therefore be faced with unnecessary trouble, and the electrical engineering profession will not advance in the public estimation.

The Board of Education and University Colleges.

IT is, doubtless, a sign of greater civilisation to find a government taking interest in the education of the country over which it rules. In the early days, governments were prone to believe their duty ended in waging wars, or in restraining the high spirits of the King's subjects with a more or less heavy hand. As what they were pleased to consider high spirits often arose from too high an education on the part of the boisterous subject, they, as a result, rather tended to discourage the spread of knowledge, and certainly did nothing actively to help it. Thus it came about that all university, and a greater part of the primary, education of this country depended on the enterprise and munificence of private individuals. Oxford and Cambridge are still self-supporting or, at any rate, sufficiently so to be independent of Treasury aid, but the increasing need for university education and the consequent establishment of many new universities (five have been founded in the last ten years) has made it necessary for special financial assistance to be given. This takes the form of a grant from the Treasury to the provincial universities (with the exception of Oxford, Cambridge and Durham), the university of London, and the three university colleges at Nottingham, Reading and Southampton.

THE Treasury, as a condition of this aid, which is independent of any that may be received from the local authorities, require the institutions concerned to supply accounts and details of their working, and these are collected in a Blue Book which has recently been issued. The information contained therein is summarised in an introductory report of the Board of Education to the Privy Council. This contains some interesting details on present-day university education. It appears that the total amount granted to university colleges in Great Britain is now £100,000, while the three Welsh colleges receive £4,000 each. Compared with the sums expended on the Army and Navy, or even on less worthy objects, this is not a very large sum, though it is sufficient to show that the claims of university education are at last receiving some recognition. These grants, moreover, stimulate private beneficence, as the numerous donations during the past year amply indicate. Further, a very rigorous inspection is made of such institutions as receive this grant, with a view to deciding whether the education provided is of a university class; all of which make for efficiency. The report further points out that specialised adult instruction by university teachers must not be considered of a university character, but only that which "is based on a broad preliminary education of wide range" and which is "conducted under conditions that enable it to become the main interest and occupation of the student." This is a view with which most will be in entire agreement. There is no objection to providing higher education by evening classes or in specialised form, but it should not be called university education. If we keep our standard of university teaching high, we cannot also fail to raise that of the primary and secondary education, so that the Board of Education is well advised to assist as much as possible all institutions that approach these ideals and to cut off university grants from the others.

London Electrical Engineers.—The following notice relative to this Corps appeared in last Friday's "Gazette":—Lieut.-Col. and Hon. Col. (Hon. Major in the Army) R. E. B. Crompton, C.B., M.I.E.E., is retired, under the conditions of paragraph 116, Territorial Force Regulations, and is granted permission to retain his rank and to wear the prescribed uniform; Major (Hon. Capt. in the Army) H. M. Leaf to be Lieut.-Col., Capt. J. H. S. Phillips, A.M.I.E.E., to be Major, Lieut. G. W. C. Kaye, A.M.I.E.E., to be Captain (July 9).

L.B. & S.C. Railway Electrification.—Confirming our anticipations of last week, we now learn that an order has been placed with the Allgemeine Elektricitäts Gesellschaft (Berlin) for supply of electrical equipment for the trains of the L.B. & S.C. Railway Co., to be used on the electrified line between Victoria and the Crystal Palace and between London Bridge and the Crystal Palace, on to Norwood Junction. The contract comprises 28 equipments, each consisting of four 150 H.P. alternating-current motors designed to operate at a pressure of 6,300-6,800 volts and a frequency of 25.

The Telephone Situation.—A recent issue of "The Times" contains a letter by Mr. H. Laws Webb, in which the author points out the inherent difficulties of providing a Government telephone service which shall at the same time be cheap and efficient. Mr. Webb suggests that instead of the Post Office completely taking over the business of the National Telephone Co. a more satisfactory arrangement would be for the company to continue the commercial management while the Government retained control over the rates charged.

Wireless Telegraphy and the Cable Companies.—Mr. Ernest L. Walford, of the Stock Exchange, London, recently communicated to "The Times" his views on the subject of Wireless Telegraphy and the action (or rather the alleged inaction) of the Submarine Companies in adopting this method of communication in combination with their cables. It may be that the cable companies have not made the public fully aware of the steps they have taken to obtain the fullest advantage from all modern means of intercommunication. We are in a position to state that, from the first, many, if not all, the companies have, through their electrical departments or by other means, kept abreast of all developments of wireless telegraphy. For some time past several of the companies have actually been operating wireless where the circumstances or necessities of the case have allowed or have needed it. For instance, the Western Isles (the Azores) have all been linked up by wireless by the Europe and Azores Co. for the Portuguese Government, and negotiations are in progress to establish wireless installations at several of the Eastern and Eastern Extension Companies' stations. The West India and Panama and other companies have wireless stations either in operation or in course of erection. Mr. Walford and the share and stockholders in the cable companies may rest assured that every step in advance is being closely observed and the fullest advantage taken of latest developments. The observations of the chairmen at the meetings of the companies have, we think, satisfied the members that the position, so far as their interests are concerned, are adequately safeguarded.

The Order of Merit—The King has been graciously pleased to appoint Sir Wm. Crookes, F.R.S., to the Order of Merit. The achievements of Sir Wm. Crookes are well known to our readers, and satisfaction will be felt that he should have been selected to fill the place in the Order of Merit left vacant by Sir Wm. Huggins. Besides discovering thallium he has done a great deal of work on radium and has covered a great part of the field of physics from the chemical side. He has been president of the British Association and of the Institution of Electrical Engineers. He was knighted in 1897.

Electrical Smelting of Iron Ore in Scandinavia.—H.M. Legation at Christiania report that the iron produced at the experimental furnace erected at Tinnfos, near Skien, Christiania Fjord, which can be manufactured at about £3 per ton, is capable of competing with the best Swedish "charcoal iron," costing from £5 to £5. 10s. per ton. The production at Tinnfos is at present 3 tons a day; when the power at the works has been increased to 1,000 H.P., 25 tons a day will be turned out. The ore, which is smelted directly in the furnace, is said to contain 45 per cent. of iron. It is proposed to develop the works for the manufacture of steel, which, it is said, can be produced at from £4 to £4. 10s. per ton, whereas Swedish "charcoal steel" of similar quality costs nearly £10 per ton. H.M. Legation are informed that there is a Swedish patented invention for the same purpose, which is said to give excellent results and to be more reliable, and that some furnaces are shortly to be erected near Christiansand.

H.M. Consul at Stockholm reports that the Swedish installation for the electric smelting of iron which is financed by the Association of Iron Workers is being proceeded with satisfactorily at Trollhättan. At the same time experiments have been resumed with the original electrical furnace at Donnarfvet, and the superintendent has officially announced that the results are even more satisfactory than those hitherto obtained, and that he considers the economic problem of dealing with ore by electricity so as to supersede that of the blast furnace to be definitely solved.

Obituary.—HARRY W. COX.—It is with great regret we record the death, on Saturday last, of a victim to the disease which has many times followed in the wake of the successful application of X-rays. Mr. Harry W. Cox, the patient experimenter whose sufferings have now terminated, had long taken a keen interest in electrical matters, and when the subject of X-rays came forward to be investigated, he from the first put his heart and soul into the work. Unfortunately, his enthusiasm resulted in his exposing himself to the dangers of these rays, with the result that first his hands, then his arms, and ultimately his face became affected by the dreaded "X-ray dermatitis." Mr. Cox, his injuries notwithstanding, continued his earnest work in the X-ray field, adding many useful and interesting instruments and pieces of apparatus to the equipment of the medical profession. Among these instruments may be mentioned an appliance for showing the depth of an embedded object below the surface of the body when seen by X rays. He was responsible for 50 patents relating to coils and other X-ray appliances. Mr. Cox's efforts were recognised in the highest quarters in the land—a fact which greatly softened the fate which was hanging over him for several years. An attempt was made to obtain for him a Civil List pension; unfortunately the Prime Minister was unable to comply with the request, but a grant of £200 was made out of the Royal Bounty Fund. At the instance of Sir William Treloar a sum of £2,800 was raised by subscription to meet, to some extent, the necessities of this pathetic case. Mr. Cox was highly respected in the world of therapeutics, and his death is mourned by many who have benefited by his experiments. The funeral took place yesterday (Thursday) at Abney Park Cemetery.

HON. C. S. ROLLS.—By the untimely death of the Hon. C. S. Rolls engineering is robbed of one of its most consistently practical devotees. The pioneer work of Mr. Rolls in automobilism contributed much to the establishment of the motor car industry in this country, a fact for which the many electricians now conducting a flourishing business in ignition apparatus must feel extremely grateful. Though not closely identified with the electrical industry, Mr. Rolls had many electrical friends who will join us in our expression of sincere sympathy with his bereaved parents.

ALFRED E. IZARD.—We also regret to record the death of Mr. A. E. Izard, which occurred on Monday last at Kingsgate, near Broadstairs. For nearly 25 years Mr. Izard has been associated with the lighter side of the electrical engineering profession in that he, first as an accompanist and afterwards in the dual capacity of accompanist and musical director, in conjunction with Mr. T. E. Gatehouse, did much towards providing that tunefulness for which the Electro-Harmonic Society has long been noted. Mr. Izard became a student of the Royal Academy of Music in 1878, a sub-professor in 1883, and professor in 1885, which position he held until his death.

PROF. THOMAS HAMILTON CORE.—We also regret to record the death of Prof. Thomas Hamilton Core, which occurred on Saturday last at Wellington, Manchester. The deceased was in his 74th year. For thirty-five years he occupied the Chair of Physics at Owens College, Manchester, retiring in 1905 as emeritus professor. Until 1881 he also supervised the more mathematical parts of the physical teaching, but towards the end of his professorship he confined himself to lecturing on experimental mechanics, and withdrew from teaching the more advanced work.

Current Topics.

Subjects of current interest dealt with in this issue include the following:—

Mr. F. Fernie contributes an article in which he deals with the laying of Cables and Ducts.

Mr. F. J. Chambers describes a new form of liquid microphone for the purpose of wireless telephony.

Mr. H. Tinsley contributes an article on "Weston Cells," in which he describes a method of rendering them portable by the use of a simple diaphragm.

We give a description of the Brown, Boveri system of train lighting.

A further account of the exhibits at the Brussels International Exhibition appears on another page.

Walsall Corporation have decided to expend £23,225 on additional plant, extensions of mains, &c.

At the meeting of London County Council on Tuesday the Fire Brigade committee presented a report on the tenders received for the supply of three electrically-driven motor (escape) vans.

A Bill to make the installation of wireless telegraphy on passenger ships compulsory was read a first time in the House of Commons on Wednesday.

The Board of Trade have issued their report on the applications made for Provisional Electric Lighting Orders during the past year.

The Municipal Council are considering eight tenders received for the concession for electricity supply in Constantinople.

Parliamentary.—A House of Lords Committee has rejected the North East London Railway Bill.

The London Electric Supply Bill, which makes the London County Council the purchasing authority of the five remaining electricity supply companies, has passed the committee stage in the House of Lords.

INSTITUTIONS AND SOCIETIES

TRAMWAYS AND LIGHT RAILWAYS ASSOCIATION.—The Official Circular of this Association for June contains, in addition to various matters relating to the Association, a copy of the Board of Trade Regulations regarding details of construction and equipment, a copy of the Proceedings of the Board of Trade and of the Light Railway Commissioners up to December 31, 1909, and a verbatim Report of the Discussions on the Papers read at the recent Tramway Congress held in Dublin on June 9 and 10.

LOCALISATION OF FAULTS ON UNDERGROUND MAINS.*

BY W. A. TOPPIN.

Summary.—After discussing the causes of faults, and the recording of earth leakages, the author describes a simple method of locating earth leakages and the apparatus he has constructed for facilitating the test.

Much attention has been given of recent years to the design and manufacture of underground cables, with the result that cable can now be procured which, if carefully laid, will last for years, giving satisfactory service with little or no repairs. It is now generally recognised that the cable system is at least of equal importance with the generating station. If information were obtained on this subject it would be found that more interruptions of supply have occurred through faults on cable networks and feeders than through all other causes combined. To ensure continuity of supply the details of a cable system must be as carefully thought out and be subject to the same intelligent care and supervision as any portion of the station plant.

The following remarks on the localisation of faults are not based on any particular theory, but are the result of the author's practical experience with a three-wire direct-current system, using single conductors, the distributors generally being laid solid in bitumen and the feeders drawn into conduits. The most fruitful source of trouble on

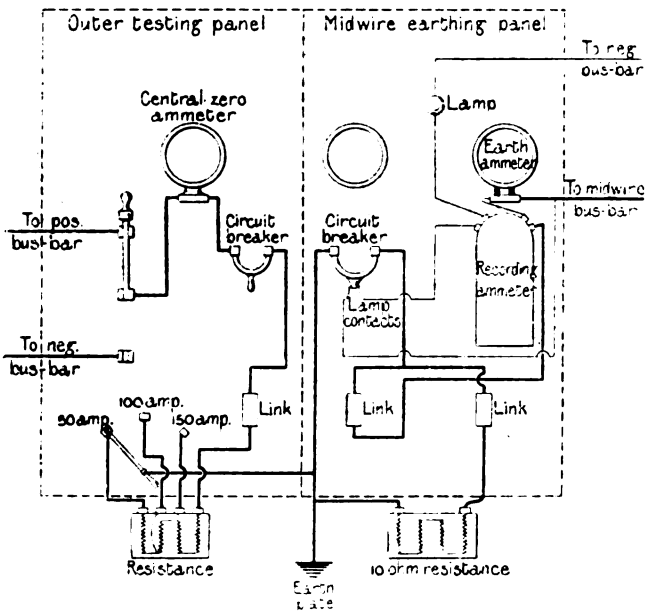

FIG. 1.

such a system is that arising from earth leakages, which may occur on either of the outer conductors or on the middle wire. As a rule these faults develop gradually, and unless localised at an early stage may result in a serious "burn-out" with possible interruption to the supply system. It is therefore wise to take steps to localise and repair a leakage immediately it begins to indicate on the earth-recording ammeter. The author is aware that some station engineers believe in allowing earth leakages to develop to a more pronounced stage before adopting remedial measures, and one engineer at least has indeed advocated the "smoke" test method of localising faults; but the author believes those who have any regard for the prestige of their undertaking will agree with him that, as the primary consideration is reliablity of supply, incipient mains faults should not be permitted to develop to such an extent as will interfere with the supply even to a single consumer. His experience shows that 90 per cent. of mains faults originate in earth leakages, and these can nearly always be located and remedied before reaching the critical stage.

Causes of Faults.—Faults on cable systems may be classified under the following heads: (1) Those due to defects in the manufacture of the cable, such as cracks or pinholes in the insulating material. (2) Those due to improper methods or careless handling of the cable when laying. (3) Those due to disturbance of the ground either by subsidence or street openings by other departments.

Recording of Earth Leakages.—On all direct-current systems where the pressure between adjacent conductors exceeds 125 volts, the Board of Trade stipulate the following conditions: (*a*) The connection with earth of the intermediate conductor shall be made at one point only on each distinct circuit—namely, at the generating station, sub-station or transformer—and the insulation of the circuit shall be efficiently maintained at all other parts. (*b*) The current from the intermediate conductor to earth shall be continuously recorded, and if it at any time exceed one-thousandth part of the maximum supply current, steps shall be immediately taken to improve the insulation of the system.

Fig. 1 shows a testing and earthing panel, the latter designed to meet the Board of Trade requirements. On the right-hand panel the middle wire 'bus bar of the station switchboard is connected through the indicating and recording ammeters, and thence through an automatic circuit-breaker to an earth-plate of ample dimensions. The cut-out is adjusted so that when the current flowing through it to earth exceeds 25 amperes the circuit is interrupted and the current is shunted through a 10-ohm resistance. When open, the circuit breaker arm closes a circuit through an indicating lamp and a relay on the recording ammeter, the latter actuating a needle to record the time during which the cut-out is open. The left-hand panel has been designed for testing the insulation resistance of the outer conductors, the method being to earth each outer cable in turn through a known resistance, and noting the resultant current. It is also used to burn out minor earths which may occur on consumers' premises. If, for example, such a leakage is indicated on the negative outer the procedure is first to disconnect the middle wire 'bus bar from earth and then to earth the positive 'bus bar, and by passing a current which can be varied by the regulating switch, the fault is burnt clear or localised by the melting of the consumers' fuses. In an industrial district where large power users are connected to the supply mains, and especially in places like shipyards and foundries where temporary circuits are often run, many troublesome earth leakages occur, and a careful study of the earth chart will enable the mains engineer, with a knowledge of local conditions, to locate most of these faults. Overhead travelling cranes with bare trolley wires are responsible for many intermittent leakages.

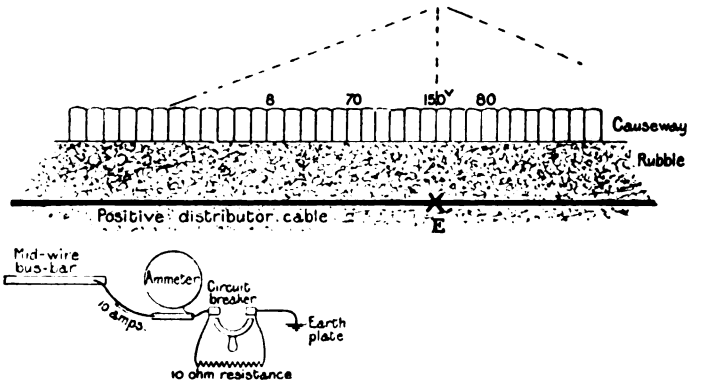

FIG. 2.

It is well known that negative cables are more susceptible to earth leakages than positive cables, and a record of the faults which have come under the author's notice during the last few years shows that fully 80 per cent. of the earths on a supply system occurred on the negative side. In almost every case of breakdown in a negative conductor the core was found saturated with moisture for 4 ft. or 5 ft. on each side of the fault, due apparently to osmotic action, while the bitumen covering, which under normal conditions is unaffected by moisture, is converted into a spongy state, quite independent of its temperature. This peculiar effect is produced on the negative cable only, and in cases of faults affecting both outer conductors, the positive core was found to be quite dry, while the surrounding bitumen was in its normal state, or only affected by the heat generated by the leakage current. A positive earth fault on a feeder cable, which occurred in a draw-in box, due obviously to a crack in the bitumen sheathing, showed a gradually increasing leakage current for a period of three weeks, and on cutting out the faulty section the moisture appeared only to have crept for a few inches along the core on each side of the fault while the bitumen was practically unaffected.

Locating the Faulty Cable on the Network.—The location of faults is rendered easy where cable networks are divided into sections with disconnecting links in convenient pillars. The proper method is to fuse each distributor cable at its feeder pillar, and in the event of a short-circuit the faulty section is automatically isolated from the system. Momentary short-circuits which disturb the pressure are not of great enough duration to melt the fuses, and are consequently the most difficult to deal with. For this reason, among others, the author is of opinion that all feeders should be provided with recording ammeters on each conductor. A defect on the middle wire is not

*Abstract of a Paper read before the Glasgow local section of the Institution of Electrical Engineers.

Digitized by Google

easy to locate, and introduces complications when an earth takes place on an outer as the leakage current from the latter may be passing to the middle wire, and no indication given of the fault.

Many methods have been employed for the localisation of faults on underground mains. In most cases the choice is limited by the type of cable and the system of supply. The author will not institute comparisons between these, but proposes to describe a simple method which he has found of service in locating earth leakages without interrupting the supply. He is not aware if the idea is novel or otherwise, but can testify from actual experience of its worth, and the chief claims he puts forward are its simplicity in operation and the absolute certainty of the results obtained by its use. Its operation depends on the fact that when an earth leakage occurs, the earth in its vicinity is charged to a potential above normal earth potential, and this potential will vary at any point in inverse proportion to the distance from the fault. Assume an earth leakage at E on a 250-volt three-wire system of distributors (Fig. 2), the current shown on the ammeter with the 10-ohm limiting resistance in circuit being 10 amperes through the fault. This gives a total resistance between the fault and the earth-plate of 15 ohms and a difference of potential of 150 volts. This pressure will be highest immediately at the fault and will diminish with the distance from the fault. It can be measured by an ordinary voltmeter, but in most cases a special voltmeter, calibrated to read down to very small pressures, is desirable. One terminal of the voltmeter is connected to a rubbing contact and the other to a good earth connection, such as a steel rod pushed into the ground at a distance of 2 yds. or 3 yds. from the cable route. Besides simplicity in operation and accuracy of results, other advantages of this method are that the smallest earth leakages can be expeditiously located without interruption to the supply; the apparatus is cheap and simple in construction, while the test may be made by any one possessing elementary technical skill. The method is applicable to any system of supply, whether direct or alternating. In the case of a two-wire supply it is only necessary to earth the unaffected conductor to give the required P.D. surrounding the fault.

The author has found in practice that it is much more satisfactory to obtain testing current from the supply mains than to employ portable batteries, as the latter require to be maintained in good order, ready for an emergency, while the discharge current may be totally inadequate for the purpose of locating a fault, unless it should happen to be a dead earth. In very few cases is it found impossible to locate faults by the method described by the author, and in these recourse has been had to the well-known but more elaborate Wheatstone bridge methods or to Murray's loop test, these, however, requiring the disconnection of the faulty section. One of the most trying faults to locate is that of a burnt-through cable which still retains its normal insulation resistance to earth. If a leakage cannot be started by subjecting the insulation to a high-pressure test, its position may be found by an elaborate capacity test from either end, or by the crude method of cutting the cable at various points along its length.

Insulation testing sets consisting of ohmmeter and generator are now universally adopted for testing mains, but the author would like to call attention to the inability of the generators in most of these sets to maintain a sufficiently high pressure when testing a cable of low-insulation resistance.

DISCUSSION.

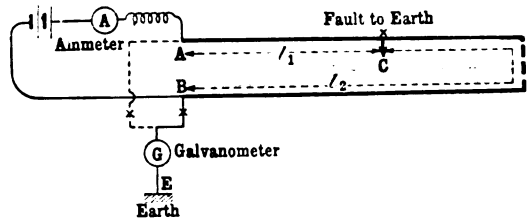
Mr. McLeod (Clyde Valley Power Co.) congratulated the author on the originality and ingenuity displayed in the Paper. He asked if the author had ever tried the system on three-core lead-covered cable and with what results. Further, would it not be very difficult to use in very dry ground, especially with wood paving or granolithic, and was it necessary to go over a considerable area with the apparatus indicated to locate a fault? Supply authorities as a rule found it better to prevent faults coming on than to allow them to develop and burn out. His company took insulation resistance tests at regular intervals. In this connection the pilot wires, such as were used in connection with Merz-Price feeder protection and telephone pilot wires, now pretty generally adopted in all first-class supply systems, came in very handy. Being more lightly insulated, they were more sensitive to any subsidence, and in that way indicated before the heavier insulated cable where and when there was a fault developing.

Mr. W. W. Lackie (Glasgow) said Mr. Toppin had referred to the important part which underground mains played in the supply of electrical energy. They represented quite one-half of the capital expenditure of the undertaking, and, further, they were buried underground and could not be inspected like plant, and when anything went wrong all evidence of the cause was generally burned away. For this reason alone it paid to adopt the very best system of cables. The arrangement in Glasgow was to have a recording ammeter on the positive and negative pole of each feeder, but also to have a shunt in series with the middle wire, on which an ammeter could be connected at any time. Each feeder was isolated and fed its own piece of network, so that the station engineer was able to report at once to the mains department what feeder or area a fault was showing itself on. Mr. Toppin seemed to condemn the drawing of bitumen cable into ducts, and the bitumen was liable to turn spongy with leakage current. The speaker asked if this were really his experience. The subject of osmosis was brought very prominently before the public some years ago. In Glasgow they experienced trouble from this without bare copper strip, and the insulation of the negative wire was practically nil. When Mr. Chamen adopted triple concentric mains he looked into this subject pretty closely, and they once thought of altering the polarity of the triple concentric mains. At present the core was positive, the next conductor negative and the outer was the middle wire. With this arrangement the central conductor would suffer from the osmotic effect, and one might have a breakdown between the central conductor and the negative, or between the negative and the outer. It was thought that if they altered the polarity of the central conductor and made it negative, and the next conductor positive and the outer conductor the middle wire of the system, that the osmotic effect would be confined to the central conductor, and, further, it would probably be protected from osmotic effect. In conclusion, he congratulated Mr. Toppin on his practical contribution to the subject of the localisation of faults.

Mr. McWhirter asked for more information as to how the tests were carried out. Mr. McLeod had advocated tests, while Mr. Lackie said "no tests." Mr. Toppin's system would be quite good while the fault was in the incipient stage. Electrolysis had always been the "black man" with cables. He thought the smoke test, burning out of the fault, was rather rough on the consumer. Lead was being given up as a covering for underground cables.

Mr. W. D. Morgan thought that on the testing panel shown there was a "dead short" circuit through the earth connection. If a pipe ran alongside the cable there might be a case where the enigneer, while using the triangle, followed the pipe instead of the cable down a side street where there were no cables.

Mr. Robertson (Greenock) mentioned that there were cases where the author's method would not do, three-core cables, for example. In Greenock there were cables under high-water mark where fault currents had varied between 1, 2 or even 5 amperes. He advocated the smoke test system, and he questioned if in Glasgow any other system would do. He referred to a method which he had found to answer very well. It was similar to a potential test and was shown in the accompanying diagram.



Calling the distance between A and C, l_1, between B and C, l_2, and the total length of cables = L = $l_1 + l_2$, then with a galvanometer connected between A and E the deflection d_1 is obtained. By connecting the galvanometer between B and E the deflection d_2 is obtained. Then $l_1 = L \cdot \frac{d_1}{d_1 + d_2}$, and, similarly, $l_2 = L \times \frac{d_2}{d_1 + d_2}$. He did not think insulation tests much good, and he did not agree with Mr. Lackie as to isolating the feeders. Distributors with dead ends could scarcely be cheaper than a linked-up system. It meant that there would, of necessity, require to be different voltages for each feeder. The best way of preventing faults was to get a good cable and lay it carefully on the solid system protected with suitable troughing.

Mr. Raphael, in a written communication, asked if the method was suitable for lead-covered cables. He instanced a similar system of fault indication in Berlin, where pilot wires were run from the feeding point back to the station to an indicator there, but that arrangement was not perfect, as the tramway currents sometimes made the indicators come out. He advocated the use of a portable set with a battery.

Mr. Sillery (Partick) advocated separate networks.

Mr. Allan advocated the use of an insulation testing set, and deprecated the use of the smoke test on account of fire risks, especially if a factory was closed for the night.

Mr. Toppin, in reply, said the method had not been tried on three-core cables, but it was quite suitable on lead-covered or drawn-in cables, if the lead had no breaks of continuity in it. It had been successfully tried on cables 2 ft. 6 in. below the surface in the dryest weather. The ohmmeter and generator method was only suitable before putting cables into commission. He had used a compass near boxes where the position of cables was apparent. Electric tramways had no effect on the test in his experience. To prevent the "short-circuit" indicated by Mr. Morgan, circuit-breakers were provided.

Telephony on Trains.—According to the "Telephone Engineer," the Lehigh Valley Railroad has decided to instal a telephone service on its trains running between New York and Buffalo, to be available at stations. Communication will be effected with the outside world at wayside stations through the telephone circuits which run along the lines.

THE COMPOUNDING OF ALTERNATORS.*

BY A. BLONDEL.

Summary.—The author describes his system of compounding alternators. The exciter rotates in synchronism with the alternator, but with a fixed mechanical phase displacement. Alternating currents are passed into the armature winding of the exciter so as to magnetise the field system and automatically raise the exciter voltage as the load increases. Details of actual installations and test results are given.

A very interesting article, by Dalémont and Herdt, on "Armature Reaction and the Compounding of Alternators" has recently been published.

After recalling M. Blondel's theory of two reactions for the particular case in which variations in permeability can be neglected, the authors of that Paper state that an excellent compounding of alternators can be obtained by compensating for the reaction due to the

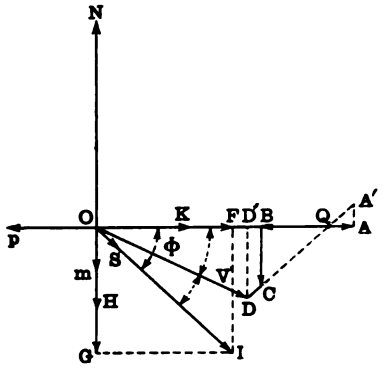

FIG. 1.—VECTOR DIAGRAM FOR THEORY OF TWO REACTIONS.

wattless component (I sin Φ) alone. In fact, the reaction due to the watt component (I cos Φ) is always very small, and serves rather to raise the voltage.

The author (M. Blondel) had already made this remark in August, 1896, at the Congrès des Electriciens de Genève: the study had even been carried further, and a system of compounding proposed.

At the Congrès des Electriciens de Paris (1900) the author expounded this method more fully. Finally, in February, 1904, he added a second exciter for the purpose of obtaining complete stability of running and a large flexibility in the regulation.

This method, which is entirely distinct from any of those described by Messrs. Dalémont and Herdt, has escaped the notice of these latter, who live in Canada, since up to the present the method has only been published in the "Comptes Rendus de l'Exposition de Liége"; but, in fact, the method has been put into practice for several years with satisfactory results.

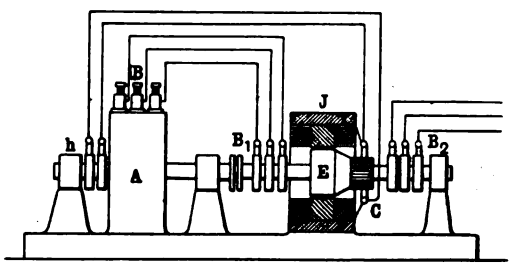

FIG. 2.—PRINCIPLE OF EXCITATION BY THE REACTION OF THE WATTLESS CURRENT PASSED THROUGH THE EXCITER.

The author, then, has thought it of interest to recall the principle of his method of compounding, and also to give some instances of its practical applications.

Let us consider the vector diagram (Fig. 1) mentioned by Messrs. Dalémont and Herdt. The problem to be solved, according to this diagram, was to regulate the excitation of the alternator by creating in the field winding, on load, additional ampere-turns proportional to the vector OG, representing the wattless component of the current (I sin Φ). This result was originally realised by the author's *reaction exciter*, the principle of which he expounded, as follows, in 1896: "The method consists in the use of an exciter of the Rechniewski type, with a small air-gap; the field windings, constructed in the usual manner, are shunt wound, and excited just enough to produce the excitation required by the alternator on open circuit; the armature, which rotates in synchronism with the alternator by a mechanical coupling, has two windings, the one winding being continuous current and exciting the alternator, and the other a compensating winding similar to the alternator winding and traversed by the same currents; the number of turns, and the points at which the current is led into this winding are so adjusted that the reaction field produced by a wattless current has the same direction as that of the main field, and strengthens it in exactly the same proportion that the corresponding armature reaction of the alternator tends to weaken its own field; in addition, the brushes are kept fixed by one of the known methods. Under these conditions, if the alternator and the exciter are both being worked below the knee of their saturation curves, it is easy to see that all the armature reactions, watt or wattless, are compensated automatically."

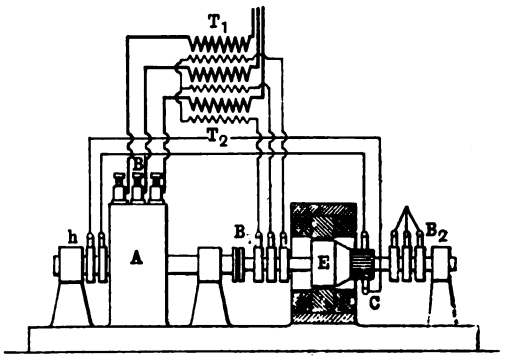

FIG. 3.—COMPENSATED EXCITATION BY WATTLESS CURRENT WITH A SERIES TRANSFORMER.

Fig. 2 represents this arrangement for a three-phase machine with rotating field. A is the alternator, B the terminals from which the currents are led to B_1, the slip-rings connected to the compensating winding on the exciter E, B_2 the main terminals, C the commutator of the main exciter winding and J the shunt winding.

It is obvious that the passing of the alternator current direct into the exciter armature is only practicable for low-tension currents; with high-tension alternators the current must previously be transformed by means of a series transformer. The arrangement is then as shown in Fig. 3, in which T_1 is the primary circuit of the three-phase transformer in series with the main circuit and T_2 the secondary. It will be seen that the three rings B_2 now simply serve to close the supplementary winding, which receives the currents from the secondary T_2 by means of the rings B_1; the rings

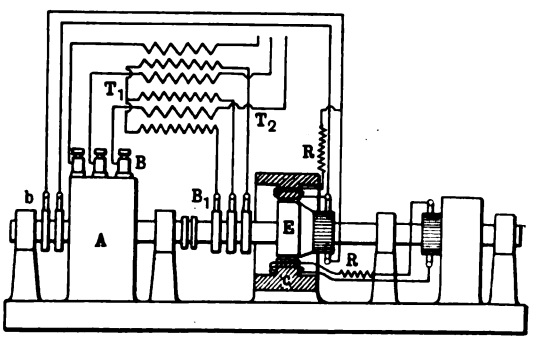

FIG. 4.—DIAGRAM OF COMPLETE METHOD; REACTION EXCITER WITH PARTIAL INDEPENDENT EXCITATION.

B_2 can therefore be dispensed with, and the joint made on the armature according to general practice. By suitably choosing the number of secondary turns T_2 on the transformer, the two armature circuits can be combined just as with a rotary converter.

Fig. 4 represents the scheme of compounding as it is actually applied. In addition to the apparatus already described, there is a small direct-coupled dynamo for a new and important purpose. This machine supplies a part of the excitation for the exciter E, and thus ensures the stability of the magnetic equilibrium of the system at all loads. It is a very small machine and always works on the same load. On the other hand, the exciter E and the transformer do not work at constant and complete saturation of the iron.

Fig. 5 shows the diagram of connections of the exciter E for a bipolar machine. In reality, it is evidently convenient for this exciter to have the same number of poles as the alternator, or else

* From the "Bulletin" de la Société Internationale des Electriciens (slightly abbreviated).

Digitized by Google

it must be driven by a multiplying gear. With turbo-alternators the number of poles is, however, almost always two or four.

Fig. 6 shows the mechanical phase displacement of the exciter relative to that of the alternator, supposed star connected.

Principle of the Calculation of Compounding by means of a Reaction Exciter.—As we have already remarked, the wattless current which flows in the exciter armature on load, due to the wattless component of the current in the transformer, must exert a magnetising influence on the exciter; we will represent it, therefore, by OG in Fig. 5, which has the same signification as the vector OG in Fig. 1. In the same manner we will represent the watt component of the current by the vector OF, at quarter centres and in advance of the vector OG. The effect of this watt component in the exciter is to assist rotation and commutation; in fact it is easy to see that this component does work and produces a turning moment: its reaction on the exciter field tends to counteract the reaction of the current collected by the brushes.

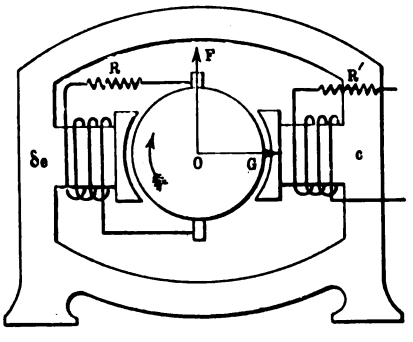

FIG. 5.—DIAGRAM OF MAGNETIC FLUXES IN THE EXCITER.

If e is the E.M.F. between the brushes of the exciter, the E.M.F. between the rings is $\sqrt{\frac{3}{8}}e$ and the E.M.F. between each ring and the neutral point is $e/\sqrt{8}$. This ratio, calculated on the assumption of sine curves, must be corrected in practice, and, in general, it is taken that the E.M.F. between rings is equal to e multiplied by a certain coefficient γ. This E.M.F. is obviously at quarter centres with OG.

In like manner there is a component in quadrature with OF, due to the cross flux of the exciter; but this component is always very feeble, on account of the small ratio that this cross flux bears to the main flux, and, moreover, there is, as we have just seen, a partial compensation between the cross flux due to the vector OF and that due to the current taken from the brushes.*

If n is the ratio of transformation of the transformer, the E.M.F. of the exciter in terms of the primary will be $\gamma e/n$.

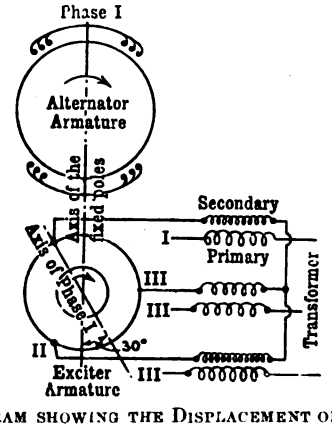

FIG. 6.—DIAGRAM SHOWING THE DISPLACEMENT OF THE EXCITER ARMATURE.

(Alternator star connected, exciter mesh connected.)

This E.M.F., generated by the exciter, is in opposition with E_0; in order to make it as small as possible in practice, the number of secondary turns is made from three to four times the primary turns on the transformer; under these conditions the fall of potential across the primary winding on full load is practically negligible. So far as the action of the series transformer is concerned, it is sufficient to assume that it produces a secondary current approximately proportional to the total primary current taken from the alternator. The watt component of the secondary current is in part converted by the commutator of the exciter, and thus contributes directly to the excitation of the alternator, and also in part produces a turning moment as has been seen above; the wattless component serves to produce a magnetising reaction proportional to the wattless component of the primary current.

It is true that, in order to drive this wattless component through the armature, a certain E.M.F. is necessary, and, in consequence, there must be a certain difference between the "wattless" ampere-turns of the primary and of the secondary, approximately in phase with OG. The author, however, ensures that this vector shall be very feeble and practically negligible by making:—

1. The self-induction of the secondary winding of the transformer very large compared with that of the exciter armature, and consequently the winding acts approximately as if it were closed on itself.
2. The greater part of the necessary magnetising ampere-turns to be furnished by a shunt winding, which will be mentioned again later; the "wattless" ampere-turns of the armature above all serve to regulate this shunt excitation, and only produce in themselves a part of the necessary ampere-turns.

The total ampere-turns on the exciter are composed of a constant part, c, due to the small auxiliary exciter, and a variable amount produced by the reaction of the wattless component of the alternator current, and equal to (in continuous-current ampere-turns)

$$K\frac{I\sin\Phi}{n}\times\frac{m\sqrt{2}}{2}.$$

$\frac{I\sin\Phi}{n}$ representing the current in each ring, m the number of conductors on the armature, and K a well-known coefficient, depending upon the number of phases and conductors.

On open circuit, *i.e.*, when I=0, there is no current in the primary of the transformer; but there is a small wattless current in the secondary, due to the effect of the exciter being short-circuited by it. This can be taken account of, once and for all, by representing it by the equivalent counter ampere-turns, and considering that the excitation ampere-turns of the exciter on open circuit are reduced to a constant amount, obtained by the difference $C-C'=c$; these resulting ampere-turns set up an E.M.F. e_0 at the brushes of the exciter.

On load the current from the exciter to the transformer diminishes, becomes zero, and then changes its sign; the resultant excitation always remains below the knee of the open circuit characteristic of the exciter; the exciter voltage e is therefore proportional to the excitation ampere-turns

$$c+\frac{Km\sqrt{2}}{2n}I\sin\Phi.$$

The ratio of transformation n is so chosen that the term $\frac{Km\sqrt{2}}{2n}I\sin\Phi$ (proportional to the wattless component of the current), with respect to the constant term c, has the value necessary to provide the additional ampere-turns to the alternator, in order to maintain (or to raise) the voltage at the terminals. In order to reduce to a minimum the reaction ampere-turns which have to be supplied by the transformer, as stated already, a shunt winding is added to the exciter E, as shown in Figs. 4 and 5. The expression for the total magnetising ampere-turns becomes

$$\left(c+\frac{Km\sqrt{2}}{2n}I\sin\Phi\right)\left(1+\frac{\delta e_0}{c}\right)$$

where δ is a convenient constant.

It will be seen that the addition of this excitation, due to the shunt winding, does not at all modify the conclusions at which we have arrived; it is even possible to give it a preponderating effect—for example, two-thirds of the total excitation. But it must not be carried too far in this direction, for the shunt winding by itself must not be relied on for the working of the system, for then the system would be unstable.

The great advantage, in practice, of this excitation taken in shunt from the exciter brushes is to reduce to about one-third the current required from the transformer and from the auxiliary exciter. This latter machine in particular can be a quite small bipolar dynamo, or the power can be taken from the continuous-current station 'bus bars when available. As for the transformer, it is much smaller than if it had to assure the whole of the excitation required by the alternator.

Voltage Regulation and Compounding of the Alternator.—The regulation of the system can be adjusted by means of the rheostats R and R'. By regulating the rheostat R in the shunt circuit the total value of the alternator exciting current can be adjusted in a certain proportion, but the relative value of the compounding effect is unaltered; in fact, this operation is equivalent to modifying the numerical value of the coefficient δ in the factor $\left(1+\frac{\delta e_0}{c}\right)$.

* The brushes being fixed in the neutral position and the pole shoes being unsaturated, the cross flux moreover does not appreciably affect the E.M.F.

Digitized by Google

By regulating R′, and hence the excitation provided by the small auxiliary exciter, the relative value of the compounding is adjusted; in fact, the value of the term c with respect to $\frac{Km\sqrt{2}}{2n} I \sin\Phi$ is thus modified.

It can be seen, therefore, that it is very simple to modify at will the compounding effect, as well as the absolute voltage of the alternator. This great flexibility and convenience of regulation is one of the characteristics of the system of compounding just described, and contributes largely to its practical value. It is also to be noticed that if for any reason the compounding transformer is damaged, the arrangement permits of hand regulation just as with an ordinary alternator. It is also to be noticed that the two operations of the regulation are exactly equivalent to those employed in the regulation of compound-wound continuous-current dynamos.

There is, moreover, an analogy between the two kinds of compounded machines, and all the known properties of compounded dynamos can be applied to the working of compounded alternators. For example, parallel working can be obtained with the greatest ease; and it is advantageous also to use equalising connections, that is to say, to connect the terminals of the alternators direct on to equalising bars, in order that their mutual synchronising action can take place freely. However the fall in potential in the compound transformers is so small that several compounded alternators on this system operate very well in parallel without equalising connections or special precautions being taken.

Examples of Actual Installations and Test Results.—The author gives brief details of actual machines compounded by his method. They consist chiefly of two-pole turbo-alternators. Test results on two of the machines are also included, and we give below a few details.

1. *Alternator:* 500 kw. 3,000 volts, 50 cycles, 2 poles. Compounding transformer: Primary, 26 turns; secondary, 64 turns (star).

Experimental Results.—Inductive load ($\cos\phi$ 0·8).

Load.	Volts.	Excitation.	Current exchanged i_2.
0 ampere ...	3,000 ...	75 amperes ..	5·9 amperes effective.
93·5 amperes ...	3,030 ...	120 ,, ...	23·0 ,, ,,

(Without compounding and excitation 75 amperes, the voltage falls to 2,350 with a load of 93 amperes.)

Non-inductive Load ($\cos\phi = 1·0$).

	Load.	Volts.	Excitation.
Fixed resistance R′ = 19 ohms ...	0 ampere ...	3,000 ...	75 amperes.
Shunt resistance R = 60 ,, ...	104 amperes ...	3,150 ..	110 ,,

	Load.	Volts.	Excitation.	i_2.
Fixed resist. = 12 ohms ..	0 amp. ...	3,200 ...	85 amp. ...	6·1 amp.
Shunt resist. = 61 ,, ...	108 ,, ...	3,190 ...	116 ,, ...	22·5 ,,

The above figures show plainly how close is the compounding effect and also the ease with which the voltage and the compounding effect can be adjusted by means of the two rheostats. They also show how small the currents exchanged between the transformer and the exciter are in comparison with the exciting current of the alternator. In this particular installation three alternators are connected in parallel without equalising connections or special apparatus of any kind.

2. *Alternator:* 500 kw., 525 volts, 3,000 revs. per min., 50 cycles. The following results have been obtained at unity power-factor:—

Load.	Volts.	Excitation.	R.P.M.
80 amperes ...	530 ...	60 amperes, 21 volts ...	3,010
140 ,, ...	530 ...	64 ,, 22 ,, ...	3,030
180 ,, ...	530 ...	70 ,, 24 ,, ...	3,020
260 ,, ...	540 ...	79 ,, 27 ,, ...	3,020

When running on its distribution system at a speed of approximately 3,000 revs. per min., the following results have been obtained:—

Load.	Cos ϕ.	Volts.	Excitation.	Current exchanged, R.M.S.
0 amp. ...	— ...	525 ...	52·5 amp., 19 volts ...	3·5 amp.
300 ,, ...	0·865 ...	525 ...	76·5 ,, 26 ,, ...	17·0 ,,
386 ,, ...	0·865 ...	525 ...	80·0 ,, 28 ,, ...	24·0 ,,
650 ,, ...	0·80 ...	525 ...	103·0 ,, 40 ,, ...	45·5 ,,

The voltage is thus practically constant. The voltage across the primary of the transformer does not exceed 2 volts on load.

Conclusion.—The chief features of the author's system of compounding are, a very great simplicity, the use of a single series transformer of relatively unimportant power, instantaneous action (due to the laminated field system of the exciter), and the ease with which the voltage can be raised independent of the compounding effect, and the coefficient of compounding regulated independent of the voltage. There is an absence of all delicate mechanism which is likely to get out of order, such as resistances operated automatically, and the operation of the system simply depends upon purely electrical and magnetic reactions.

THE BROWN-BOVERI SYSTEM OF TRAIN LIGHTING.

It is not surprising to find that from its very introduction the use of electricity for train lighting has increased by leaps and bounds. Not only did its employment make it possible to discard the gas containers and other deadweight, but its greater safety in case of accident has been often made apparent. To provide a train with light is, however, not an easy matter, and several systems have been devised, some of which consider each coach as a unit, while in others all the energy for lighting is supplied from an auxiliary set on the engine. In the former case the dynamo is driven from the road wheels, and special arrangements have to be made to ensure the voltage being constant over a wide range of speed.

Among the firms who have devised a system on these lines may be mentioned Messrs. Brown, Boveri & Co. This company designed a marketable arrangement so long ago as 1902, and now has over 3,100 equipments, lighting over 4,000 passenger cars, in use.

With a few minor alterations it remains the same to-day as it originally was. Messrs. Brown, Boveri & Co. early recognising that the system of electric train lighting which ought to be developed was that which provided a separate equipment for each carriage. This, of course, has the advantage that each carriage forms an independent unit, and one which can be used if necessary as part of a train in which gas or other lighting is also used. In addition to this general advantage, the particular system evolved by the firm possesses, it is claimed, the special advantage that no regulation or adjustment is necessary to enable the carriage to be used in fast or slow trains, or to enable it to be employed for long or short lighting periods. Such flexibility of working calls for an equipment provided with a regulating apparatus which can satisactorily deal with such onerous requirements.

In a train-lighting system the battery must be protected from overloads, and the voltage of the lamps must remain constant, independently of changes in the speed of the train. These conditions cannot be fulfilled by any one machine, and in the Brown-Boveri system the work is performed by a standard generator working in connection with a special regulator.

Current is only supplied from the battery when the train is at rest or running at speeds less than 15 miles per hour. Above this speed the lamps are supplied direct from the dynamo, which at the same time charges the battery, if not already fully charged. The dynamo is switched out and replaced by the battery when the train speed drops below the minimum mentioned above.

As regards the apparatus used on this system the dynamo is a continuous-current shunt wound machine of very simple construction, and is freely suspended either from the carriage framework or from the bogie truck. The tension on the belt (which is the usual drive employed) is produced either by means of the weight of the dynamo itself or by springs. Seeing that the dynamo must generate current in both travelling directions, a means of reversing the position of the brushes is provided, so that with each change of travelling direction the brushes are automatically shifted into the correct position corresponding to unvarying polarity. The bearings are constructed with ring lubrication. The dynamo is dust-tight, and in consequence of its simple and strong construction, requires a minimum of attention—in fact Messrs. Brown, Boveri find that the experience gained with the 2,000 equipments already supplied shows that the upkeep costs are almost negligible.

The battery is provided to maintain the lighting during stoppages of the trains; in consequence, its size depends principally on the number and duration of the stops. Usually the battery is so dimensioned that the lighting can be maintained by its aid alone for 7 to 10 hours. It consists of a fixed number of cells, according to the lamp pressure, these cells being arranged in groups and mounted in a wooden case, in such a manner that without any considerable labour they can be placed in, or be removed from, the battery container which is arranged on the long side of the carriage.

The automatic regulator is for the purpose of controlling the pressure of the dynamo and keeping it independent of the travelling speed, so that on the one hand the battery can be charged, and on the other the supply to the lamp circuit maintained. Directly the train starts, the dynamo excites itself, whatever the direction of travel, and as the train speed increases there is a proportionate increase of pressure. As soon as it reaches the battery pressure the dynamo is switched both on to the battery and on to the lighting circuit by means of the automatic switch (C) shown in Fig. 3. As the speed of of the train increases, the dynamo pressure tends to rise. This is prevented by switching resistance into the shunt circuit. The automatic variation of the resistance in circuit is carried out by means of the regulator R, in which the contact sector A rolls over a number of contacts corresponding to the number of subdivisions of the

Digitized by Google

resistance, in this way varying the shunt current and thus the pressure of the dynamo. The first contacts are connected to the operating magnet of the paralleling switch, the others to the resistances. The regulator R consists of an electromagnet between the poles of which a bobbin, O, fixed to the contact sector A, capable of partial rotation is placed. The field produced is partly due to an exciting winding, M_1,

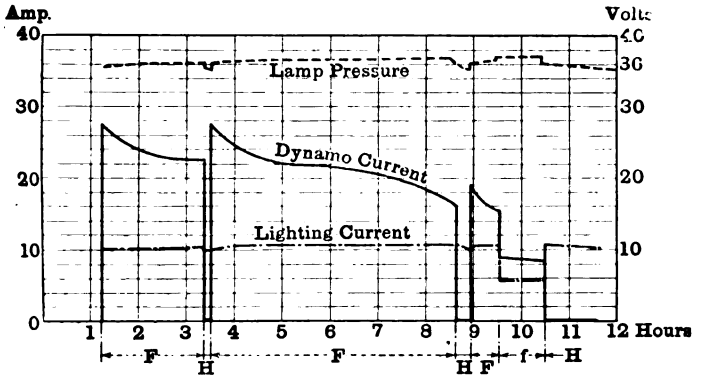

FIG. 1.—CURVE ILLUSTRATING THE CHARGING OF A COMPLETELY DISCHARGED BATTERY DURING THE LIGHTING PERIOD.

in circuit with the movable bobbin O and the shunt of the dynamo, and partly to an exciting winding, M_2, which receives its current from the battery and whose magnetising effect is in the same direction as that of winding M_1. A third exciting winding, M_3, carries the lighting current and produces a magnetising effect in the opposite

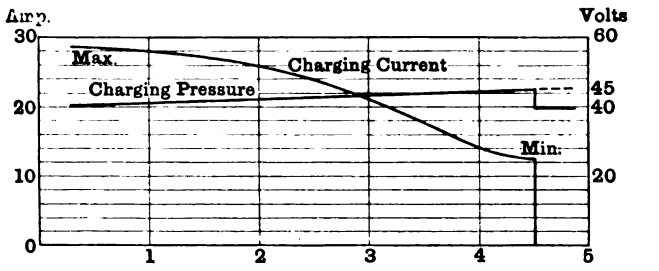

FIG. 2.—CURVE ILLUSTRATING THE CHARGING OF A COMPLETELY DISCHARGED BATTERY WITHOUT CONSUMPTION OF LIGHT.

direction to that of the windings M_1 and M_2. The magnetic field produced by the combined effect of the windings M_1 and M_2, or M_1 and M_3, tends to turn the current-carrying bobbin O, whose movement is opposed by the spring F. This spring is so arranged that it exerts a constant pull on the bobbin O.

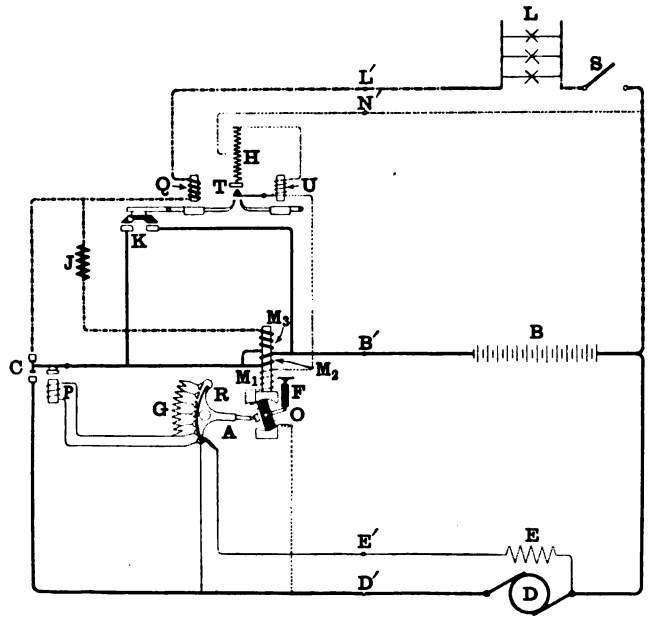

FIG. 3.—COMPLETE DIAGRAM OF CONNECTIONS SHOWING THE INTERNAL CIRCUITS OF THE AUTOMATIC REGULATOR.

The demands made on such a train-lighting equipment are very varied, depending upon whether it is installed on fast or slow trains, and if the journeys undertaken are by day or night. The following are the two extreme cases: A fast train stopping at few stations, and travelling by day only, there being in consequence no considerable demand for light. A slow train stopping at many stations and travelling by night, with, of course, a large demand for light.

In the first instance, once the dynamo has completely charged the battery, its services are no longer required, and the function of the regulating apparatus is to prevent further production of current, as should charging of the already fully charged battery be continued it would be detrimental to the latter. Therefore the output of the dynamo must be quite low, and this under the difficult conditions that it is running for a long time in consequence of the few stoppages at stations and of the greater speed at which it is running on account of the high rate of travelling.

In the second case the dynamo must not only keep the battery continually in a fully charged condition, but during the journey it must in addition supply current directly to the lamps. The machine must thus generate a large amount of electrical energy, as it is imperative that the battery should not become too far discharged, because it could be damaged even more in this way than by being over-charged. Here, again, the production of the electrical energy occurs under unfavourable circumstances, because the working period of the dynamo in consequence of the many stoppages is relatively short, and, further, the speed at which the machine is running is low on account of the slow rate of travelling of the train.

The diagrams (Figs. 1 and 2) show how the charging of a completely exhausted battery takes place, firstly during a journey without any outgoing energy being taken, and secondly on a journey where lighting is used.

It will be seen from the above description of the Brown-Boveri system that the operation of the regulating device is one of the chief features of the system. The principal object of this arrangement consists in the regulation of the shunt rheostat by means of the rolling sector A, in Fig. 3. The ends of the resistance coils are led to wedge-shaped contacts arranged in a row upon which the contact sector rolls. The contact surfaces are made of silver to avoid oxidation.

ELECTRIC CABLES.*

LAYING CABLES AND DUCTS, AND RECORDS AND COSTS.

BY F. FERNIE.

(*Continued from page 438.*)

Summary.—The author describes in a general way the methods followed in laying cables in ducts, on the solid system or simply armoured: also in the shafts of mines. In conclusion, records are considered and the allocation of costs.

LAYING CABLES AND DUCTS.

General.—The most difficult problems in main laying are met with in the principal streets of large towns, and the electric supply engineer, coming, as he does, last of all in the demand for space, sometimes finds but little choice in the matter. Tramway lines may occupy a large part of the carriage-way, and there may be main and distributing gas and water pipes, with services taken off them at various levels; drains of all kinds promiscuously laid, telephone and telegraph pipes, and tramway feeders. In the midst of this medley accommodation must somehow be found for the electrical distributors, usually on both sides of the road, and in many cases provision has to be made for feeders, pilot wires and street lighting cables in addition.

Feeders are often laid in the roadway, as they need not, in the natural order of things, be again disturbed; but it is nearly always best and cheapest to lay distributors in the footpath, for the following reasons:—

1. All service leads are shorter, and therefore cheaper.
2. Cables can be laid much shallower than in the roadway.
3. The ground will be much drier round the cables.
4. There is less excavation, and the work can be done more cheaply and quickly.
5. A proper draw-in system for distributors is almost impossible if installed in the carriage-way, on account of the great cost of the necessarily heavy pits and covers for draw boxes and service connections.
6. The cables are more readily accessible for connections and repairs.

* Copyright. All rights of reproduction reserved.

Digitized by Google

7. There is generally more room, as gas and water pipes are nearly always in the carriage-way.

8. The permanent reinstatement is usually cheaper than that of the roadway, and can be done once and for all. A trench in a roadway takes time to settle, and if filled up in wet weather has to be gone over several times afterwards to get a good road surface.

After deciding upon their situation, one of the first questions that arise is the minimum safe distance which should separate the cables from gas or water pipes. The mains engineer should be particularly careful to avoid gas pipes, on account of the danger of explosions if they are injured by electrolysis, and naturally the owners of all other pipes are as much concerned about the safety of their property.

If a pipe is within 2 in. or 3 in. of a cable it may be burnt through by a fault, but even at a distance of 4 ft. or 5 ft. it is not immune from danger. The diagram in the section on fault localising shows how the potential of earth varies, as the distance from a fault increases, so that at a radius of 7 ft. there is not sufficient potential gradient to cause any danger. It is, however, as a rule, impossible to keep 7 ft. away from all pipes, and on a properly maintained network it is quite unnecessary, because a fault can be located so quickly that there is no time for much electrolytic damage to take place before it is disconnected. Six inches of intervening earth is reasonable, but even this cannot always be maintained, in particular where cables are laid in footpaths above cellars, owing to the existing gas and water services. One advantage of *insulating* ducts and troughs is that they may be laid with safety much closer to other pipes than those made of clay, for instance.

Apart from the risk of damage due to the proximity of the various pipes, the question of their respective accessibility should be carefully considered. Electric cables must not be laid above any existing drains or underground works, and to guard against this the trial holes should be probed with a steel bar, to make certain that the sub-soil is clear.

When it is necessary to cross other pipes, this should be done at right angles; if the cables cross near a joint in the pipe this should be at the socket end, so that it can be re-staved at any time.

Before opening any ground to lay cables, notices and plans must be sent to the various authorities. These may include the gas and water people, the Postmaster-General and the road surveyor. It is as well to bring the foreman and a few men to the job the day before the gang commences, and let them open up trial holes on the proposed route in order to find a clear course. Often the position of existing pipes can be ascertained previously from the different authorities, but in old streets this is never the case, and a number of pipes, particularly drains, will be discovered of which there is no record.

When the main body of men arrives, the track should be marked off ready, and they can at once get to work. We do not consider it a good plan to let each navvy open up a section of trench by himself, because the pace will then be regulated by that of the slowest. It is better to mix the men's work up as much as possible, so that it is not easy for them to recognise when the too energetic members of the gang should be advised to slow down.

The length of trench that can be opened at one time depends on the nature of the traffic and on the police regulations, but usually 100 yds. or so is sufficient. The work must be safely barricaded, and for this purpose wooden trestles and planks are to be preferred to iron spikes and ropes, which are sometimes dangerous. All bridges, &c., over the track should be carefully fenced. Corporations are particularly liable to claims for damages, and generally have to pay, so that extra time and trouble on barricading, &c., is not wasted. Canvas screens should be used to protect the passers-by and shop windows from the fragments that fly when a hard macadam or concrete road-bed is broken up. It is also well to make a note of all broken windows in a street before beginning work, as fraudulent claims for damages have sometimes been made. The men must be impressed with the necessity for reporting any pipes they may accidentally damage, and they should not be penalised for this, otherwise they will cover up the damage with soil, and when, later on, it is inevitably discovered the cost of rectifying it will be much greater than if it had been reported and admitted at once. The position of gas and water services can generally be found from the stop cocks, and should be chalked on the wall for the men's guidance.

Ducts.—The trench being opened, some fine soil is riddled into the bottom to serve as a bed, and the pipes are then laid in and jointed. If rows of single pipes are used, they should be kept everywhere apart with the joints staggered, and distance pieces of wood or broken clay pipe put in here and there. This prevents a bad short circuit between cables in adjacent pipes, and represents an advantage over composite ducts. All ducts must be laid so as to drain into draw boxes, and any dips or hollows in them are quite inadmissible. The slope must be such as to drain from one box to another, or high in the middle, so as to drain both ways into a box at either end. Two feet of depth is enough for cables laid in carriage-ways, or less if they are concreted. In footpaths it may be much less, and we consider that under flagstones the pipes containing the cables should be visible as soon as the stones are lifted. There will then be less risk of *accidental* mechanical injury. A spirit level is used in setting each length of duct so as to keep the "run" right.

If concrete is used as a protection, it may be made up of 1 part cement to 6 or 7 parts sand and metal (by volume). If the concrete is intended to save the pipes from a crushing strain, like that caused by a steam roller, it should be placed underneath and packed well round the sides and between, as well as on the top, so as to form a kind of bridge. If it is intended merely as a protection from picks, it need only be placed on the top and at the sides. In any case, the concrete should have a smooth surface, and thus be easily recognised by any workman opening the ground later as something to be respected, and not to be smashed up as a casual obstruction.

A smoke testing apparatus, similar to that used for drains, should be used on every length of pipes laid before filling in. This is a very sensitive test, and will show up any bad joints or fire cracks. When this test has been made, the ground is filled in, first with sifted earth, which is carefully packed round the sides and between the pipes; more earth is then shovelled on and lightly rammed or punned—very carefully at first or the joints will be spoiled. When the trench is nearly full the ramming should be as vigorous as possible, and two men should be ramming for each man shovelling in soil. In dry weather more stuff can be got back if water is mixed with it, and the surface of a macadam road is generally washed in with water.

"*Solid*" *System.*—When laying cables "solid" there are one or two points to notice. The troughs are first laid in, jointed and bedded on sifted earth. The saddles can then be put in place, being stuck down with little patches of bitumen poured in hot. If this be done the cables must be drawn in *alongside* the troughing, and afterwards lifted into position.

Those who have not had actually to do this kind of work always suggest that the drum of cable should be rolled along over the trench and the cable paid off direct, forgetting that it has, at least in towns, to be threaded under pipes crossing the trench at right angles. The other method is to draw the cables into the troughs and afterwards to slip the saddles under. Perhaps the troughing is kept cleaner by the first method, as loose soil is very liable to be knocked into it at all stages of the operation. To prevent this, strips of canvas are often laid along the sides of the trench.

Before filling in the bitumen everything should be perfectly dry and clean. We think, if lead-covered cable is used, there should be no braiding on it, because this may act as a capillary passage for moisture to travel along the cable, and also because it is nearly impossible to dry it properly after a shower of rain; and, since the trench cannot be kept open indefinitely, the work cannot be satisfactorily carried out in showery weather. Braiding would appear to be far more necessary for conduit work, where the cable may have to be drawn in and out several times, and cannot be examined after it is pulled in.

Digitized by Google

If the cable be pulled alongside the troughs first, it can all be examined for injury, and cleaned whilst it is being lifted into its final position. The saddles should be from 1 ft. to 2 ft. 6 in. apart, being nearer together the more flexible the cable.

The first pouring of bitumen should be very hot and thin, so that it is sure to get underneath the cable; if it is not hot enough it is very liable to chill and partly solidify on first coming in contact with earthenware or lead, and thus air spaces may be formed. After this bitumen has hardened a little the troughs may be finally filled up with bitumen not so hot, the right temperature being ascertained by its appearance. The cables are liable to buckle with the heat if the troughs are filled right up at first, and they must be watched during the first filling, and, if necessary, pressed into their proper position with sticks. If the troughing is covered with bricks or tiles, they are generally put on whilst the compound is hot, so as to make them stick in position. If the troughs are laid on a gradient, it is necessary to start at the bottom and to work up hill when filling.

Where "solid" cables enter a brick pit they must be led through glands of some kind, since the bitumen will always tend to flow, even at ordinary temperatures. Asphalt forms a suitable material for the glands; but wood should be avoided if possible, as it always gets wet, and the cable may then be damaged by either electrolysis or chemical action.

The last two or three feet of the cable outside the pit should not be laid "solid," but in a pipe; this prevents it from being sharply bent where it leaves the "solid" trough, and it is held

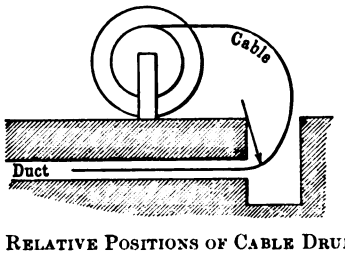

Fig. 1.—Showing Relative Positions of Cable Drum and Draw Box.

rigid. If the cable has to be often handled it is sure to give way just where it leaves the "solid" should this precaution be neglected.

Armoured Cables.—Armoured cables are the easiest to deal with. After they are laid in position, two or three inches of soil is sifted over them and the protecting boards then put on. It is said* that armoured cables should not be laid in clay, as it attacks the armouring. Our own experience is the reverse of this, and we should suppose that the bed of sand, recommended as a remedy when the soil is clay, would form a natural drain in the ground, and result in the accumulation of moisture round the cable, thus affording an opportunity for many dissolved substances to be brought into contact with the cable, some of which might be harmful.

Drawing-in Cables.—If the ducts have not had yarn threaded through as they were laid, they must be wired so that the hauling rope can be drawn in. This is done by pushing a No. 14 or 12 gauge iron wire, bent into a hook at the end, into the duct from either side, and when they meet in the middle the wires are twisted in opposite directions until they catch. An 80 yds. run of ducts can easily be wired in this way. Lengths of canes screwed together, as used for drains, are also useful, especially for very long lengths, and when additional cables are being subsequently drawn in.

When the hauling rope is ready the drum is mounted on jacks, or on its carriage, a few feet from the draw box and behind it, which prevents the cable from being rubbed against the edges of the duct or pit (*see* Fig. 1). Men are stationed to revolve the drum at the proper speed and watch that the cable does not foul anything when being fed into the duct. With a heavy cable a wooden batten is used for this, as shown by the arrow in the figure, and of course the pulling is done very slowly.

* "Practical Notes on Electric Mains."—B. L. R. Lee.

A heavy cable must be liberally greased as it goes in, petroleum jelly being excellent for this purpose, as it has no injurious effect on the lead.

It is preferable to attach the *core* of the cable to the loop formed at the end of the rope. This is done by dividing up the copper strands into two bundles, which are passed through the loop in opposite directions and then bound back on themselves with copper wire. If the duct is wet, a mop should first be pulled through to clear it. The actual pulling may be done by hand or with a winch. Hand pulling is generally the quickest, but for long lengths of heavy cables a winch is necessary.

When drawing in by hand the men should be well spread out on the rope, and should be taught to time their efforts, so that they pull together.

When adding to the number of cables already in a duct, it is better, as mentioned above, to pilot the hauling rope through by means of screwed rods, as a wire may twist about among the cables, so that the new cable is threaded amongst the others, which may not only damage them at the time, but may also prevent any individual cable being withdrawn at a future date.

Cables, particularly those with impregnated braiding, sometimes stick to the pipe or other cables, and cannot be immediately pulled out. The sticking is not confined to one place, but is due to adhesion along the whole length. The following device will often overcome this difficulty: An iron wire is pulled through the duct and a loop formed at one end, which is passed over the sticking cable. If the wire be now pulled from the other end the loop is pulled through, encircling the cable, and cuts away the adhering compound (Fig. 2). If there is a bend in the pipe near one end, the cable

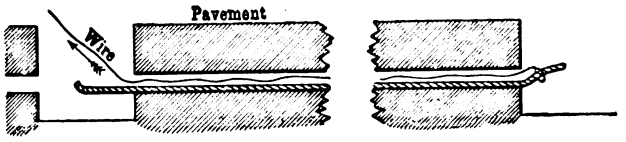

Fig. 2.—Diagram showing Method of Freeing an Adhering Cable

drum should be mounted at the opposite end, so that only a short length has to be pulled round the bend.

Mining Cables.—The installation of mining cables depends on the character of the mine, depth of shaft, &c. The simplest way of dealing with the shaft cables is to hang them from a special suspender at the top, but this is only applicable to armoured cables in short shafts. The armour, carrying as it does the whole weight of the cable, is subjected to a continuous strain, which may in time stretch it so that the insulation is impaired. This method, although cheap, is not to be recommended as the most permanent, but if the cage guides are wire ropes and there are no stays to cleat the cables on to, there may be no choice in the matter. It cannot, however, be used in narrow or very deep shafts. One advantage is that falling bodies are unlikely to damage it, owing to its having a certain amount of give and take.

A suitable suspender is described by W. R. Morton.* "The suspender best suited for the job is in the form of a cone, bored in the centre to take the cable over the armour. Over the half rounded top of the cone the armour wires are bent back and taken down the outside. The outside smallest diameter of the cone should be sufficient to permit all the armour wires to lie side by side without overlapping. This cone, with the armour wires correctly bent into place, sits in a taper seating of the same taper as the cone and provided with wings bored to take the D links of the supporting chains. The seating should be carried up above the top of the cone and the cup thus formed filled with bitumen or other waterproof compound to prevent corrosion at this point."

Another method, not always possible, is to instal the cables "solid" in wood casing filled up with bitumen. A successfu instance of this method is at Parton Collieries, Whitehaven, an armoured paper, lead sheathed cable being dealt with in

* The Electrician, October 29, 1909.

Digitized by Google

this way.* Each length of casing is filled solid with bitumen before the next length above is fixed. Owing to the difficulty experienced in filling the casing the bitumen should be made very hot and fluid. There is a difficulty in keeping the casing compound tight, on account of the quasi-hydrostatic pressure exerted by it, especially when the height is considerable; but this trouble can be overcome by the insertion of wooden glands at intervals. We have seen instances of the wooden capping having been burst off by the weight of bitumen, even with quite moderate vertical distances.

Shaft cables may also be installed in iron pipes, and although this affords an excellent mechanical protection at first, when the cables may be sufficiently "wavy" to grip the pipes at the sides, they will eventually straighten owing to their own weight, and the top suspension should thus be designed of ample strength for this ultimate condition.

Joints should be avoided, but in deep shafts, where they are a necessity, the cable lengths should be ordered so as to bring the joints at headings, or, if this is not possible, a special chamber should be cut in the wall, big enough to give plenty of room to a jointer and mate. If the joint must be made on the wall of the shaft, the cable both above and below the joint should be cleated with several good long cleats, to take all weight off the joint, which should be protected by a stout wooden fender. A variety of methods are employed to instal cables in the roads. G. G. L. Preece, in "Electric Cables for Collieries," says: "Where there is a good bottom to the roads and no danger of floor movement, a splendid permanent job can be made by burying the cables underground, out of harm's way from tubs running off the line. In non-fiery mines these troughs can be filled solid with bitumen. The usual plan with single cables is to run the two conductors along opposite sides." Cables are frequently suspended to the roof or to timber props along the sides. The suspenders should be designed to break away easily if roof falls occur, and should have a large bearing surface. The closer they are put together the better, and the cable should be allowed to lie fairly slack between them. The suspenders are made of leather or impregnated yarn or canvas, and may be held by hooks or nails driven into the timber. Earthenware insulators are also sometimes run, or a shelf may be cut in the sides to carry the cables.

No special difficulty presents itself in making joints in underground cables. In fiery mines sweated joints cannot be made, and clamp fittings in joint boxes are generally used. "Safety" cables have been designed for mining work which are supposed to prevent any sparking taking place when a live cable is cut. "The general method is to provide a small auxiliary cable in parallel with the main conductor, which, in the event of a fall cutting the cables, is arranged to break either before or after the main conductor, and in each case actuates a magnetic cut out, which opens the main circuit."†

Records of Mains and Cables and Allocation of Costs.

The importance of accurate records of underground mains and boxes cannot be over-estimated. On a large network, plans have to be referred to many times daily. The methods adopted by large undertakings have generally been built up from some very simple beginning, which has been elaborated as the necessity for accurate plans came to be recognised. Most systems in use bear a family resemblance to the one described below, with variations in detail.

A number of skeleton maps of the district served are first obtained. On one may be indicated by a coloured line all the distributors, with different coloured circles representing feeding points, disconnecting boxes, network fuses, &c., and a line in some distinctive colour may be drawn joining up the fuses, and thus indicating the limits of each feeder district. This map will be used for obtaining a comprehensive view of the whole network when planning extensions or alterations, and also when splitting up the network to locate faults.

A second map may have all the feeders drawn on it, a third may show all the public street lighting, and a fourth the high-tension cables, feeding sub-stations or buried transformers. Obviously the more "mixed" the supply system is the more maps would be used. The maps are all ruled into numbered squares corresponding to sections of the 10 ft. scale Ordnance maps. Thus any street or cable on which information is required is first looked upon the skeleton plan, which gives the number of the Ordnance map on which it appears. These skeleton plans are conveniently kept clean by hanging them against the wall one behind the other, and allowing them, when not in use, to roll up into a box, exactly like a roller blind.

The Ordnance maps, mounted on strong linen with bound edges, are kept in a series of drawers, arranged so that any particular number is readily found. On these are drawn all the ducts, manholes, cables, &c., different kinds of ducts or methods of laying cables being distinguished by employing different coloured inks. All service lines and buried joints are clearly shown, with as much detail as possible. The scale on which the boxes and cables are represented is sufficiently accurate to measure up the position of a joint, say, within 1 ft.

Where there are a number of cables crossing each other, or several joints at disconnecting boxes, transformers or sub-stations, or in any case where the scale of the Ordnance map is too small for the drawing to be clear, a reference number is given corresponding to a given page in a sketch book, where all the details are drawn to a larger scale and dimensioned. These books are kept in their proper order in a bookcase, so as to be readily available.

The cross-sections of all cables are marked on the Ordnance maps and the numbers of houses inserted where known, so that a new consumer can be located on the map and measurements taken of the length of service line and any extension of main required.

For new work, or alterations, the mains engineer writes up, preferably in a carbon copy-book, the particulars, such as section and number of cables, polarity of service, method of installation, number and size of boxes, &c., and gives it to the foreman in charge, together with a tracing from the Ordnance map showing the route to be taken, and also includes in the instructions a job number for cost-keeping. On the completion of the work this is returned by the foreman to the engineer, who notes on it any alteration from the original design, signs it and passes it on to the draughtsman, who enters the particulars on his maps, together with the measurements and sections he has taken during the progress of the work. The sheet is then handed on to the costing clerk, who checks from it the actual orders received for material bearing the particular job number, and if the material given out tallies with the work shown on the sheet the latter may then be destroyed. The clerk should also work out the cost of labour per yard of trench opened, and should enter up the date at which the work was done and the names of the foreman, jointers, &c., employed on it. The costs books are stored and the outsides dated, and if the date of the completion of all work be entered on the Ordnance maps, the particulars of any work can readily be referred to in the costs book bearing that date.

If the meter department keeps the "balancing" cards for a three-wire or multiphase system, the instructions sheets must pass through that department before going to the costing clerk, so that a record may be kept of the polarity of the new services.

To ensure the return of all the sheets issued, the mains engineer enters the number and title of each job in a book when issuing the sheets, and checks their return by this book. The highest accuracy should be aimed at, and hardly any detail is too unimportant to note. A knowledge of the number, size and position of pipes and other works in a street is frequently required, and it is thus useful to keep in a special book drawings showing sections of streets, or parts of them, which the undertaking has had occasion to open up when laying cables. One of the most difficult of a mains engineer's duties on a large supply system is to allocate all the time and material to their proper accounts. Thus, some of the work has to be allocated to capital account, and this must again be subdivided into mains

* G. G. L. Preece, "Electric Cables for Collieries," "Iron and Coal Trades Review," 1906.

† A. T. Snell, "Electric Motive Power." For detailed information on safety cables and mining work generally the reader is referred to this book in "The Electrician" Series.

Digitized by Google

extensions proper and services; then, in the maintenance account, renewals of cable must be distinguished from ordinary up-keep, chiefly on account of the income tax charges. There are also public lighting capital and maintenance accounts, and other work the cost of which is recoverable from consumers or other authorities, and probably sub-divisions of some of these.

Thus, even on everyday extension work involving services, the time and material has to be analysed and allocated to two different accounts.

The foreman in charge of a job should be the only person to issue orders for materials for that job, and should mark them all with the job number. The return of all unused or scrap material to the stores should be done through him, and his returning notes also numbered, the storekeeper having instructions to refuse all material returned unaccompanied by an order. These orders come back to the mains engineer from the stores, and are signed and allocated by him. Similarly, the foreman numbers the time sheets of the men, which are then allocated by the mains engineer. Charges for cartage are similarly dealt with, so that it will be abundantly clear (on an extensive network at least) that great care must be given to the booking up of costs if accurate and instructive figures for future guidance are to be obtained. The method of arriving at the proper tariffs to impose on a public supply system depends essentially on the correct allocation of all expenditure.

(To be continued.)

THE DESIGN OF OIL-BREAK SWITCHES.*

BY FRITZ DEHLER.

In high-tension electrical work the oil-break switch has found a large field of usefulness. The present article contains some notes relating to details of construction employed by a well-known German firm, who were early in the field as pioneers in the manufacture. The point which is kept constantly in view is the advantage to be derived from that form of design which places the live contacts at the bottom of the vessel containing the oil, the cables being connected up through openings arranged at the bottom of the case containing the switch. This plan was first suggested when it was proposed to combine the switch with replaceable fuses. Obviously this would be awkward and even dangerous if the contacts were arranged at the top, whereas on the other system the fuses can be mounted inside the cover, which is free from any live contacts. Therefore, as soon as the switch is opened and the cover raised, it is possible to set to work at once on replacing a fuse. An ammeter can also be combined with the switchwork and mounted on the same base, the whole constituting a complete substitute for a motor panel on the switchboard. It can also be combined with a minimum cut-out, which is mounted on the top of the cover, and keeps the switch closed so long as current passes. A further design includes an automatic maximum cut-out, which is likely to be useful on 10,000 volts; oil switches, combined with fuses, are possibly suitable for 5,000 volts, but for higher voltages they could only be used to control very small areas, and even in those cases only very small currents could be carried by the fuse.

One form of design is shown in Fig. 1. This could be mounted on a pedestal, or, as is often found convenient, a number of these could be mounted side by side round the room, each switch being placed in a separate cellular compartment. This switch consists of three parts, the portion *a* to the bottom of which live contacts are connected by means of suitable insulators, the portion *b* which contains the switchwork proper, and the cover *c*. The bolts holding the porcelain insulators at the bottom, end at the knife contacts *d*, which receive the spring contacts of the movable switchwork. This latter consists of a framework *e*, which is capable of vertical motion, and carries the contact springs mounted on insulators. The switch is worked from the outside by a lever, which can be moved through 180 deg., and is connected to the inside mechanism by a series of links. The releasing magnets *f*, which constitute the maximum cut-out, are immediately opposite the armatures *h*, when the switch is closed; if the current should exceed a certain limit, the armature is attracted and causes the releasing mechanism to open the switch. An opening is arranged in the cover, through which it is possible for anyone to see from the outside whether the switch is on or off by means of an indicator worked by *i*. At *k* two safety valves are placed.

These switches are suitable both for mining work and also for central stations, 68 of them being installed in the municipal works at Cologne, the whole being arranged in separate cellular compartments. Other methods of mounting the switches are used, the choice depending naturally on the circumstances of the case.

It is quite likely that automatic cut-outs in combination with oil

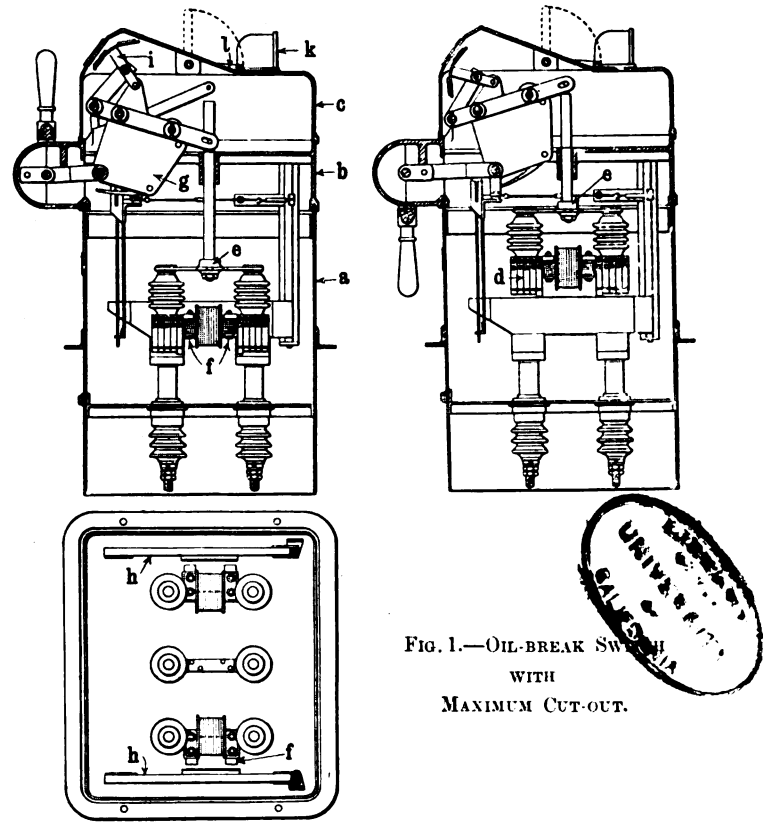

FIG. 1.—OIL-BREAK SWITCH WITH MAXIMUM CUT-OUT.

switches will be in greater demand in the future, and will be used in place of fuses. The advantage of such a combination lies partly in the fact that the circuit can be re-closed immediately, if desired, without the loss of time involved in replacing a fuse and partly also

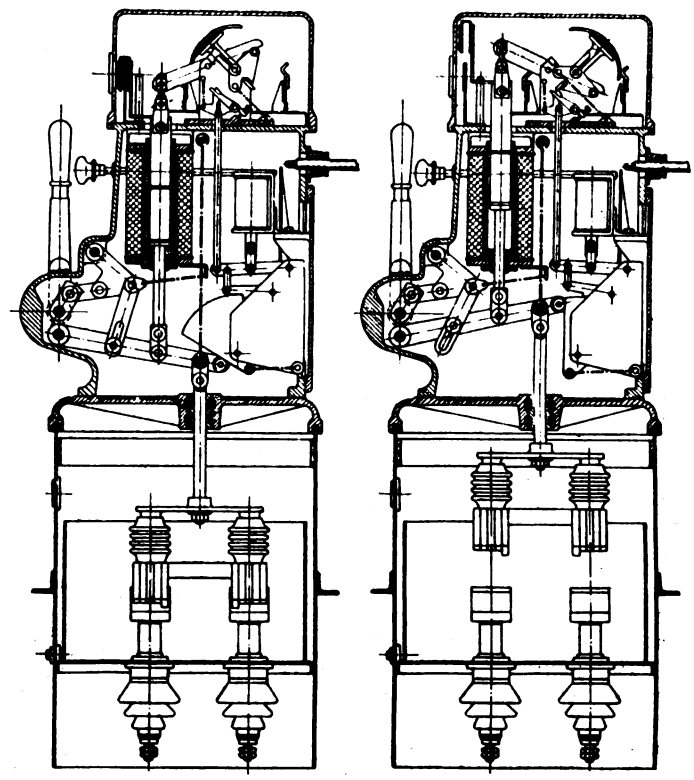

FIG. 2.—OIL-BREAK SWITCH FOR REMOTE CONTROL, SHOWN BOTH OPEN AND CLOSED.

in the consideration that it operates with much greater certainty with a double break, whereas a fuse merely blows on the one pole. Moreover a fuse requires a somewhat uncertain length of time in

* Abstract of an article in the "Elektrotechnische Zeitschrift."

Digitized by Google

order to break the circuit, and this may or may not be an advantage. The oil switches with direct maximum cut-out should be so designed that, if replaced on a continuous short-circuit, the switch automatically opens again at once, irrespective of the position of the hand-operated lever. All types can, of course, be combined with minimum cut-outs, which are specially to be recommended for use with high-tension motors as a safeguard against an accidental stoppage.

Another type of switch is one that is suitable for operation from a distance, drawings of which are shown in Fig. 2, the contacts being arranged, as before, at the bottom, and all the parts connected with the moving cores of the operating coils being in an easily accessible position at the top. The contacts being made at the bottom, it is convenient to arrange a small doorway in the lower half of the pedestal, by means of which access to the interior is possible. This arrangement is adopted in the Gutehoffnung mine at Oberhausen, where 16 switches are used, which can be automatically connected and disconnected, all the connections being made below the switch case. Very similar arrangements are made in the central station at Dortmund, where 44 switches are arranged in two rows for 5,000 and 10,000 volts. In this case, on the switchboard gallery there are two panels, to which the connections for the remote control of these switches are made, the transformers being placed on the floor below. In this way the connections are taken direct from the transformers to the bottom of the switches, with a consequent saving of space and of unnecessary and possibly dangerous lengths of cable-runs. In fact, the advantages of the arrangement by which the contacts are made at the bottom of the oil-containing case are so great that for all types of work requiring switches of this sort this form of design may well be adopted.

THE CHAMBERS LIQUID MICROPHONE.

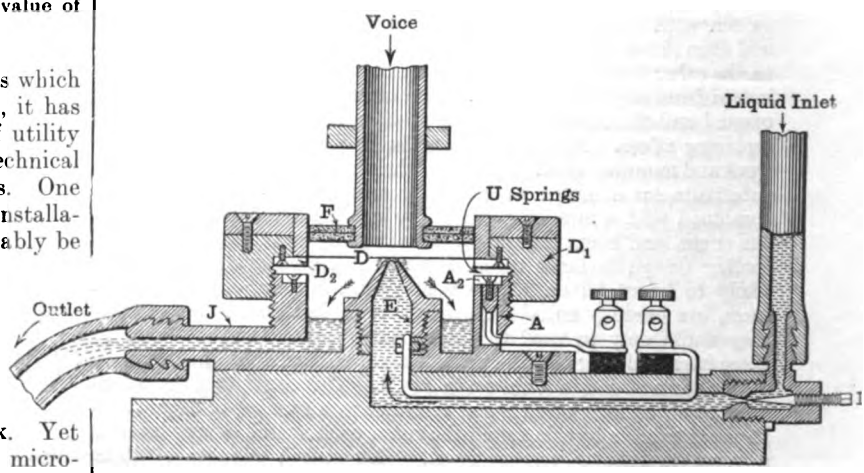
BY F. J. CHAMBERS.

Summary.—The author, after expressing some interesting views upon wireless telephony in general, proceeds to describe a novel form of transmitter. The H.F. current is led through an electrolytic path of small dimensions, so arranged that its resistance is varied considerably by the vibrations of a diaphragm, the liquid being maintained in a state of continuous flow. The advantages include absorption of energy, faithful speech reproduction, and constant normal resistance with facilities for adapting this to suit requirements. Models have proved capable of taking energies up to the value of 500 watts. Practical results are described.

After prolonged investigation of the elemental factors which go to make up a Hertzian wave telephone equipment, it has come to be the opinion of the writer that the field of utility open to this class of communication is divided, by technical and commercial considerations, into two distinct parts. One of these depends on the short distance robust form of installation, cheap to manufacture, and which can unquestionably be put into the hands of the unskilled person; and the other requires the use of more complicated forms of apparatus, for long distances, which need the attention of trained operators. Even the most sanguine inventor will admit that neither of these has as yet been evolved in really practical form, though most has been done in regard to short-distance work. Yet in this case the customary combination of the carbon microphone, which controls small energies, with large initial generating power, strikes the technical mind as being scientifically incongruous, and seems to suggest that the true solution of the problem lies in combining the carbon transmitter with what has yet to be discovered, namely, a generator of electric oscillations with the required properties, which deals with energies of the same order as the microphone; or, still further, a "generator microphone." Although the writer is at present working in the latter direction also, it is the immediate object of this article to describe one form of variable resistance instrument which, it is hoped, will eventually supply a need in the second or long-distance form of station.

In order that the wireless telephone for skilled operation may become of commercial value, it must be able to compete on reasonably favourable terms with the small power telegraph. It should have, let us say, a working range of a hundred miles at least. To effect this, if the controlling factor be a variable resistance instrument, it must be capable of dealing with an energy of the order of some hundreds of watts, and the range of control actuated by the voice must be wide. For wireless work it must be constant in its action, *i.e.*, it must impose a load on the circuit which varies only by reason of the influence of the sound waves. In dealing with large currents it is the practice of many workers to use a solid form of variable resistance instrument, such as a carbon microphone or combination of microphones, in which the destructive heating, due to the absorbed energy, is combated by some form of artificial cooling, water or a hydrocarbon being employed. The resistance of the microphonic contact, however, is well known to be of indifferent constancy, and it is principally for this reason that microphones are so frequently "burnt out," so that, in the present instrument, the writer has preferred to pass the oscillatory current through an electrolytic path, which has a constricted portion of high resistance, one or more dimensions of which is varied by the excursions of a vibrator actuated by the voice. In order to absorb the considerable energy necessary, this variable electrolytic resistance is kept in a state of continuous flow, so that a cold supply is constantly replacing the liquid heated by the current. It is clear that a change in the dimensions of the constricted portion of the liquid will, in general, produce a change of the velocity of the liquid along the constricted part of its path, and consequently, even when the resistance of portion is altered positively by change of volume, it will also be further altered indirectly by the resulting change in the velocity of the liquid. These two changes must be arranged to act in unison, for in some cases the temperature coefficient of an electrolyte is as high as 2 per cent. for 1°C. variation. Experimental work, extending over some 12 months, has determined that the most practical form of instrument is that embodied in the figure. Many varieties of valve were tried, including several forms of vibrator appended to a diaphragm, but tests showed that it is most advantageous to employ the diaphragm itself as one boundary of the constricted portion.

The figure shows, in cross section, a complete instrument.



CHAMBER'S LIQUID MICROPHONE.

A metallic diaphragm, D, is mounted upon a ring ebonite holder, D_1 in contact with a metal ring, D_2, secured to the latter. The underside of the holder is turned out, and a female thread chased upon the inner side. The ring is screwed upon A, the body of the apparatus, by means of this thread. Inverted U springs serve the double purpose of taking up the backlash in this thread and making electrical connection between the diaphragm and a second ring, A_2, secured to the ebonite body; from this ring a lead is taken out through the wall of the body to one terminal. The diaphragm thus forms one electrode, and the other is shown at E, a tubular piece of metal with an upper nipple. The liquid supply is led through a fine adjustment valve, I, to the centre of the lower electrode, passing through the latter and the constricted portion between the diaphragm and its lip, and is collected in an annular reservoir formed in the body of the vessel, A, from which it

Digitized by Google

passes by an outlet pipe, J. The lower electrode is connected by a lead passing out through the body of the vessel to another terminal. The flow of liquid is controlled by the fine adjustment valve, I, and the distance between the diaphragm and the lower electrode is adjusted by revolving the diaphragm holder. A speaking tube concentrates the sound waves upon the diaphragm, and F is a disc of felt which confines these, whilst allowing the holder to be revolved.

The head of liquid was fixed by experiment at from 3 ft. to 4 ft., and a shallow supply tank, of large capacity, is arranged accordingly. As the instrument is primarily intended to be used with high-frequency currents it is unnecessary to make provision for electrolytic decomposition, and it is obvious that the liquid must not be raised to boiling point. In practice, the velocity of flow is adjusted so that the liquid is withdrawn from the influence of the normal current at a temperature not exceeding 80°C., thus a safety margin of 20°C. is left for variations. When the microphone is installed in a wireless station, the energy in the antenna is approximately measured, and the speed of flow arranged to correspond with that portion which is to be allotted to the microphone. The resistance of the instrument is then adjusted by trial and varying the conductivity of the electrolyte, to suit the other electrical characteristics of the circuit. These two are permanent, leaving only the diaphragm adjustment which has been found easy of operation by the aid of a permanently installed hot wire instrument. The constancy of these is remarkable, an experimental instrument has repeatedly been left overnight with the liquid turned off, and found to be in perfect adjustment next morning directly the flow was started. It is possible to use very thin diaphragms of large diameter, for the liquid is a most efficient damping agency for the tendency of the diaphragm to swing in its own period. The speech reproduction is exceedingly good, and resembles a voice speaking in a space surrounded by thick curtains; there does not appear to be any trace of the metallic sounds so prevalent in most large current microphones. In order to get an idea of the range of variation the instrument was tested against a Bell telephone transmitter of equal resistance with a single dry cell in circuit, and the comparison was favourable to the liquid microphone. The flow during this test was measured, with the instrument in working adjustment, and shewed the latter to be capable of absorbing an energy of more than 250 watts. This has since been surpassed, and the latest model gives every indication of reaching 500 watts.

Tests have been carried out under peculiarly unfavourable circumstances with a type of generator which produced a hiss representing, probably, a 10 to 20 per cent. variation, and, though the hiss was preponderant over the speech, light tapping with a wisp of thin paper was loudly reproduced. It is hoped that there will shortly be an opportunity for testing this instrument in combination with an arc form of "silent generator," when good results will be expected.

The development of the invention is not yet mature, and further simplifications and capability are expected, but sufficient experience has been gained to permit of the construction of reliable instruments by those who regard the wireless telephone for skilled operation with favour.

ELECTRIC TRACTION IN THE ST. CLAIR TUNNEL.*

Summary.—A detailed account is here given of the operation of the single-phase installation in the St. Clair Tunnel of the Grand Trunk Railway, the cost of power under electric working, the maintenance of the equipment and the features of the power station plant being described.

The St. Clair tunnel of the Grand Trunk Railway has been electrically operated since May 18, 1908, and the severest requirements of the service are said to have been met very successfully by the single-phase system. The equipment † was furnished by the Westinghouse Electric & Manufacturing Co. The length of the tunnel from portal to portal is 6,032 ft. The open tunnel approach on the Port Huron side is slightly over 2,500 ft. in length, while that on the Sarnia side is nearly 3,300 ft. in length. The total distance between the American and Canadian summits is 12,000 ft., or about 2¼ miles.

The specifications for the electrification of the tunnel service stipulated that the installation should be capable of hauling a 1,000-ton train through the tunnel from terminal to terminal in 15 minutes, that in doing so the maximum speed should not exceed 25 miles per hour and that the minimum speed when ascending a 2 per cent. grade should not be less than 10 miles per hour.

The single-phase system was chosen for this work on the score of economy in operation. Preliminary figures showed the first costs for the two systems to be about equal if no battery were installed. The estimates, including batteries, were slightly favourable to the direct-current system. However, the increased first cost with a battery would have been large in either case because of the nature of the load with frequent high peaks and short intervals during which charging could be done. The guaranteed efficiencies of the two systems without batteries indicated a considerable saving in the cost of power by the use of the alternating-current system. The distribution losses and the use of current for rheostatic control lowered the relative efficiency of the direct-current system. Preliminary guaranteed figures for the power consumption for one locomotive trip hauling a 1,000-ton train through the tunnel were 141 kw.-hours for the single-phase system. In practice, considerably better figures of performance than those guaranteed have been obtained.

The electrical equipment includes six three-motor locomotive units fed with 3,300-volt, 25-cycle current generated in a steam turbine station and distributed by a catenary supported copper wire.

Operating Statistics.—The St. Clair Tunnel Co. have furnished some comparative figures for steam and electrical operation which are of interest, indicating as they do in a general way the relation between important items of operating costs. These data refer to two years' operation—one before and one after electrification. Although the amount of traffic handled during these two years was not identical, the service performed was sufficiently similar for purposes of approximate comparison of figures.

The cost of coal with electrical operation was 39 per cent. of the cost of coal under steam operation. A part of this saving is due to the greater economy of the electrical system so far as coal consumption is concerned, while another large part of the saving is due to the fact that it was necessary to burn anthracite coal in the steam locomotives that formerly operated through the tunnel, while ordinary coal or even slack is used for the power plant.

The total service charges, including all items that are charged by the railway company against locomotive service, but not including fixed charges, indicate that this charge under the electrical operation is about 60 per cent. of the charge under steam operation. If, however, the fixed charges, including both interest and depreciation on equipment, are added in each case, it is found that the total charge for locomotive service under electrical operation is approximately 84½ per cent. of the charge under steam operation.

If a comparison be made of fuel costs under steam operation with the cost of electrical energy delivered at the trolley under electrical operation, it is found that, disregarding fixed charges, the cost of power delivered to the locomotives under electrical operation is 39 per cent. of the cost of the fuel under steam operation. If, however, the fixed charge (and depreciation) due to the initial investment for the electrical generating plant and distributing system be added to the charge for electricity delivered at the locomotive, this charge then practically equals fuel cost under steam operation. This indicates that the saving is effected in other items than that of cost of power delivered to the two locomotives in the form of electrical energy in one case and of fuel in the other. One of the large items in this saving is in the maintenance and repairs to locomotives, which for the years under comparison indicates the electrical cost to be about 55 per cent. of the steam cost. Other items chargeable to steam operation, such as the coaling of locomotives, water supply, &c., do not appear at all in the charges for electric locomotives.

Locomotive Maintenance.—Three locomotives are available for use in the tunnel and switching service. At present the entire traffic is handled by two locomotives, each of which consists of two half units. The half-units are duplicates in every respect, and are equipped with the multiple-unit system of control. Each half unit is mounted on three axles driven through gears by three single-phase motors with a normal rating of 250 H.P. Inasmuch as the motors have a very liberal overload rating it is possible to develop 2,000 H.P. with two half units. In a test made on a half unit using a dynamometer car it was found that a single half unit would develop a 43,000 lb. draw-bar pull before slipping the wheels. The locomo-

* Abstract of an article in the "Electric Railway Journal."

† An illustrated description of the installation appeared in THE ELECTRICIAN, Nov. 27, 1908.

Digitized by Google

tives have a maximum speed of 35 miles per hour, but they are never called upon to operate faster than 25 miles per hour to handle the full number of trains.

An annunciator system has been installed in the inspection shed in connection with the 3,300-volt trolley wire to provide against accidents. Ordinarily the section of trolley wire inside the shed is disconnected from the trolley line outside. When current is desired to move or to test a car a hook switch installed about 10 ft. above the floor at one end of the building is closed to connect the interior and exterior trolley wires. Within the box of this switch an earth connection is provided so that when the knife of the switch is pulled open, to cut the shed trolley wire off from the line, the trolley wire within the car house automatically is earthed. An annunciator bell rings at 15 second intervals to warn the men while the 3,300-volt trolley is alive.

A regular programme of inspection is followed, and each half unit is kept in the inspection shed for 12 hours every three days. In addition to this short inspection each half unit is kept in for more thorough care for 24 hours once every 24 days. Thus the units are in service 80 per cent. of the time, which is considerably more than is possible with steam locomotives. The shed staff includes a foreman, two day and one night inspectors, one wiper and one overhead linesman whose services are also available for trolley work.

It has been found necessary to turn the locomotive tyres once every 12 months. This is on account of flange wear rather than hollowing of the tread. The flange wear is attributed to the low centre of gravity of the unit. Once every 30 days each locomotive is turned around so that the flange wear may be evenly distributed. The motor or journal bearings have given no trouble. The armature of each of the three motors drives its axle through a pinion with 16 teeth and a gear with 85 teeth. The life of these pinions is from 50,000 miles to 60,000 miles and some have run 64,000 miles. None of the gears has yet been renewed after two years' service. Whenever a pinion has run more than 30,000 miles, and the wheels are removed for any purpose, a new pinion is put on so that the wheels may not have to be removed unnecessarily.

The standard Westinghouse galvanised sheet-steel pantograph shoe is used, one on each half unit. The average life of these shoes is about 3,000 miles. The shoe is adjusted to have a pressure against the wire of 7½ lb. in the winter and 5 lb. in the summer. These low contact pressures are made possible by the limited speed of 25 miles per hour at which the trains operate. Shoes with copper wearing surfaces were tried with the idea that they would not wear the wire, but as no apparent advantage was realised and as their life was much shorter than that of the galvanised steel shoes, the trial was abandoned. The steel shoes apparently do not wear the wire so much as the copper shoes. This is attributed to the reduction in friction when dissimilar metals are used. A spring balance is used when adjusting the pantograph tension. Such adjustments are needed very infrequently, but if any undue flashing is noted during operation the tension is inspected and usually it is found that the pantograph spring has become weak or that the joints in the pantograph are stiff.

Operation.—When the electric locomotives were first put into service classes of instruction for the men who had been operating the steam locomotives were held every afternoon for two months. The men are enthusiastic over the change to electric operation. The locomotive crews are made up of two men, an engineer and an assistant. The assistant spends his time in looking over the electrical apparatus in the cabs of the two half units while they are in operation, and when not thus engaged he rides in the rear half unit. Formerly two brakemen were required for each train passing through the tunnel. The smoothness with which the trains are handled has now made it safe to operate with but one brakeman.

A round trip through the tunnel, including the terminal switching when a train is handled in either direction, requires a run of about 10 miles. The freight trains are made up so as not to exceed 1,000 tons each, and all cars are inspected before passage through the tunnel. The average mileage for each locomotive is in the neighbourhood of 2,700 miles per month. The maximum monthly mileage is 3,540 miles.

An indicating ammeter in each locomotive cab serves to assist in keeping the demand on the power station within a safe maximume The locomotive engineers are required not to let the motors of on. half unit exceed a maximum of 3,500 amperes. There are 17 running positions on the controllers. The first, second and third notches are only for switching, coupling up a train and other purposes where slow speeds are desired. The fourth to the 20th notches, inclusive, are running notches, and the controller can be left on any of these, according to the speed that is desired. The engineers become very adept at gauging the amount of power required when starting trains of various loads. When using the ammeter it becomes possible to accelerate the train and to notch up the controller as the current tends to drop. If a train will not start on 3,000 amperes, or less, per half unit the crew is instructed to look for trouble in the air-brake system.

Trolley Maintenance.—The trolley circuits for the entire electrified zone are normally all in one electrical section. Switches are provided at each tunnel incline for cutting off the yards from the tunnel section, if such sectionalisation should ever be needed. Since operation was started there have been practically no electrical troubles or mechanical defects in the trolley circuits. At one time a high brake wheel on an especially large car earthed the trolley wire in the tunnel and opened the breaker, but the trolley wire itself was not damaged enough to interfere with the continued operation of the same train after the brake staff had been bent out of the way. Apart from three of the porcelain spool insulators that were cracked when installed, the trolley wire insulation and suspension have given no trouble.

Within the tunnel the messenger cables are insulated from the conductor wires. The messengers are carried on porcelain spools and the trolley wires are supported from the messengers by special wood break hangers 3 in. square and 15 in. long. The effective insulating length of these hangers is about 5 in. If a porcelain insulator breaks down and allows the messenger cable to earth on the tunnel shell, then the wood break hangers are put under electrical stress and the weakest one begins to smoke. As stated above, three such breakages have occurred. In each instance the smoking wood insulator was noted in time so that repairs were made before service was interrupted. A tunnel patrolman is always on duty inspecting the tracks.

The pantograph shoes are lubricated with a mixture of cheap grease and graphite. This lubricant distributes itself over the trolley wires and so coats them with grease that ice has never yet formed to a thickness sufficient to interfere with regular operation.

Connections between the power station switches and the conductors and the track return in the tunnel are made through lead-covered cables for the feeder and bare copper return cables. The cables pass from the power station in underground ducts for a distance of about 150 ft. to a shaft leading down to the tunnel bore. An extra lead-covered cable, with end bells ready for quick connection at both ends, is available in case the feeder cable gets damaged.

Westinghouse gravity type lightning arresters with metal arcing points are used for protection of the trolley and messenger wires in the electrical zone outside the tunnel. The metal arcing points of these arresters, which are mounted on the steel catenary bridges, afforded a convenient perch for birds, and until precautionary measures were taken the breakers not infrequently were opened by short circuits caused by the birds alighting on the arcing points. The bodies of the birds would carbonise and afford a path to earth for the current, so that the fuse stick would not fall and disconnect the arrester. The circuit-breaker at the power house would thus open, and the lightning arrester would weaken and let the heavy insulator fall. This has been effectively provided against by adding a perch for the birds directly above the metal arcing points, an ordinary two-wire porcelain cleat being supported from one end only by a small metal bracket.

Telephones.—In installing the telephone circuit, cable was used throughout, and no part of the line is carried on poles, the object being to avoid any mechanical interference with the service. So far the telephone has given uninterrupted service.

Power Station.—The generating station is located in Port Huron on the St. Clair River front, about 150 ft. distant from the line of the tunnel. The boiler house equipment includes four Babcock & Wilcox boilers. The tubes are arranged 21 wide in order to secure quick steaming, and three drums provide a large hot-water storage capacity to assist in maintaining steam pressure under excessive demands. Underfeed stokers are used, and on account of the great variations in the load a fan 11 ft. deep by 3 ft. 5 in. wide, driven by an enclosed vertical engine, is used to accelerate quickly the fires of each group of boilers.

While no trains are in the tunnel the load on the station is about 400 kw.; but when a freight train passes into the tunnel and starts to climb the incline a peak load amounting to about 2,000 kw. is suddenly thrown on the turbine. This overload makes a heavy demand for steam, and it is necessary for the boilers to be forced immediately or their reserve capacity would be exhausted and the pressure fall below a good operating point.

The interaction of the various parts of the steam supply when excessive load comes on the turbine is as follows: Attached to the supply line is a pressure line extending to a valve located in the boiler room. The diaphragm in this valve is under two pressures. On one side is the 200 lb. pressure of the live steam main and on the

Digitized by Google

other side is the 125 lb. pressure of the auxiliary main. A balance lever serves to keep the valve in equilibrium. When the heavy demand comes on the steam line to the turbine, and the pressure in that line falls, the valve is thrown out of balance and its movement opens the throttle of the engines which drives the forced-draft fan. Normally a difference in pressure of 4 lb. will operate this valve. As the load on the turbine continues to draw heavily on the boilers the steam pressure falls and the valve feeds more steam into the fan engine until the fan is driven at full speed. With the coming on of the load the fuel is also fed more rapidly, the stoker control valves being driven through a system of belts operating from the flywheel of the fan engine.

When the control valve for the fan engine was first installed the high-pressure tap was made from the main steam header in the boiler house. The valve then lacked sensitiveness, and so to improve the service the live steam tap was made at a point in the steam line close to the turbine throttle. Thus the valve is affected by the additional drop in pressure caused by the increased load and the resistance of the header and turbine connections. In addition to making the valve more sensitive this change in location of the pressure tap has reduced the temperature in the valve. Formerly the value diaphragms lasted only two or three weeks, but since the longer pressure line has been used the life of the diaphragms has been increased to three or four months.

A separately fired Foster superheater is installed between the two batteries of boilers. This superheater can raise 36,000 lb. of steam per hour at 200 lb. per square inch pressure to a final temperature of 587°F., which corresponds to a superheat of 200 deg. The grates are hand-fired and the temperature of the steam is controlled automatically by means of a thermo-couple in the steam outlet of the superheater. This thermo-couple is connected to a relay with a large solenoid which opens and closes the valves to a hydraulic piston. These valves move dampers in the air ducts and thus regulate the draught. In practical operation the regulating devices have been found to control the temperature very closely, notwithstanding the great variation in load to which the power plant is subjected. The superheater is of especial value because on periods of normal and low load the piping and turbine are kept highly heated by it, and thus initial condensation is greatly reduced at the time of the sudden demands.

The two Westinghouse-Parsons turbo-generators which comprise the main units of this plant are three-phase machines, but by the specifications are required to furnish their full-rated load of 1,250 kw. from a single phase. Each of the turbine units is capable of handling the entire load and so one machine always is held in reserve. Each turbine regularly handles peaks of from 2,000 kw. to 2,300 kw. single phase, which last for four of five minutes at intervals of about 15 minutes. This phase also carries the lighting load. The other phases carry the load of the pumping and auxiliary apparatus, amounting to 200 kw. With normal traffic through the tunnel the daily output of the plant is about 10,000 kw.-hours. The maximum output for one day was 12,000 kw.-hours and the highest peak load 2,750 kw. This plant has been in continuous service without any interruption in supply since April, 1908.

The main generators are cooled by means of air drawn through the coils by vanes mounted on the rotor. The supply of air for this cooling service as originally installed was all taken from out of doors. An independent supply duct serves each turbine. The ducts are short, and so air is taken into the turbine generator at practically the outdoor temperature. Formerly difficulty was experienced in severe weather because of frost accumulating on the air intake screens and cutting down the circulation. To provide against this condition an opening was cut through the side of each duct. Now, in cold weather, the turbine cooling air is taken from the basement. The circulation of this air through the turbine generator also serves to warm the building.

Each turbo-generator set was at first used on alternate days, but now the load is shifted from one machine to the other twice a week, because of the stresses set up in a turbine when it is warming or cooling. A Tirrill voltage regulator set is a very essential part of the regulating equipment of the plant. This set is connected with the locomotive phase of the generator only and maintains it practically constant at 3,300 volts. When a heavy train goes through the tunnel and a maximum load comes on the railway phase, the other two phases get considerably out of balance, and so, to keep the voltage on the lighting supply constant, all the lighting transformers are connected with the locomotive phase. The smaller pump motors, machine shop and other motors are all of the three-phase induction type operating directly across the 3,300-volt line, and so they are not unduly affected by the locomotive phase being out of balance with the two unloaded phases.

On account of the widely variable nature of the load it is necessary to keep an especially careful watch over the turbine governors and emergency valves. A systematic method of testing these safety devices is followed. Whenever a turbine unit is shut down, and the load is changed from one to the other twice a week, the emergency valve tripping device is given a service test. The engineer moves the governor rod so that the speed of the turbine is increased, meanwhile watching the frequency indicator and noting at what frequency the emergency valve closes. The valve is set to open at 10 per cent. above normal speed, and it is thus put to an actual test twice each week.

ELECTRIC DRIVE IN TEXTILE MILLS.*

BY A. MILMOW.

Summary.—The author first discusses the comparative cost of the power plant in a textile mill fitted with electric drive and in one where a mechanical drive is adopted. He then considers the cost of operation, mentioning the various advantages of the electric drive.

It is the purpose of this Paper to deal especially with the employment of electric power, derived from hydroelectric systems of distribution, for the operation of textile mills, and to treat the subject from a broad, general viewpoint, with particular reference to its commercial aspects, and especially in comparison with the old forms of steam drive.

First Cost.—The references which follow will be to new mills especially equipped for electric drive, insofar as first cost is considered, and not to mills already equipped with steam power. The figures are based on a plant of 25,000 spindles on moderately fine work, requiring a power equipment of about 1,000 H.P., a group drive throughout and 2,300-volt motors being used. Details of the cost of the various items of the installation for electric drive and for mechanical drive are tabulated by the author, and show the total cost of the power plant for steam drive to be about £16 per horse-power and for a similar electric equipment about £7 per horse-power, or a saving of £9 per horse-power where the electric drive is used. All the costs are included in these estimates, though it is quite usual for advocates of steam drive to take for its first cost only the costs of engines, boilers, piping, &c., neglecting such important items as chimneys, belt-ways, condenser reservoirs and other items essential to steam drive, but not required where a mill is electrically driven. This difference in cost should enter into the cost of power, taking the interest and depreciation at 12 per cent., the lowest possible figure. However, it is obvious that it this same amount of money were expended in producing textile machinery the earnings would certainly exceed the 6 per cent. included in this figure as an interest charge.

Cost of Operation.—The cost of steam power in a textile mill is very difficult to determine, since, owing to the very wide variation of power, only a very thorough and detailed set of indications will give a fair average of the amount of power. Moreover, to obtain perfectly accurate results such tests should extend over a long period, embracing all the seasons of the year, as there are many variable quantities involved, such as the temperature of the mill, the humidity of the air and even the nature of the cotton staple. These factors cause an extreme variation of power during, say, a year's period of as much as 20 per cent.

On account of using the same boilers for power and for other purposes it is difficult to obtain accurate figures on the cost of dye-house, heating and slasher operation in a steam-driven mill. In electrically-driven mills it has been possible to segregate these costs. The cost of heating a 10,000 spindle mill is, for the climate of the Piedmont region, about £50 per year, and as this size mill will use about 500 H.P., the cost of heating may be taken as about 2s. per horse-power per year. This figure is for a boiler of just sufficient capacity for the work. Similarly, the cost of slashing is found to be 6s. per horse-power per year. Of course, this figure varies with the class of work, but it applies to work using an average of about No. 30 yarn. The figure commonly taken in estimating steam horse-power cost is about 16s. per horse-power per year, which is entirely too high. For these reasons it is very difficult to determine any accurate cost of the steam power on the horse-power-year basis. When a mill is changed to electric drive, the opportunity of improving speed, &c., is usually taken advantage of, and the mill is generally reorganised to an extent that precludes the possibility of a direct comparison. It has been found, however, that where the machinery in a converted mill has been kept intact and the speed kept constant, and where accurate records of engine indications prior to the change have been kept (which is rarely done), a saving in the power required is effected,

* Abstract of a Paper read before the American Institute of Electrical Engineers.

Digitized by Google

though most mills when making this change take the opportunity afforded of improving the production in one or more ways and thus increase the power required.

Assuming the price of electricity to be £5 per horse-power per year for 11 hours per day, 306 days per year, and assuming a saving at equal production of 15 per cent. in power (which I consider conservative), the cost at which steam power must be generated to equal the price of electric power will be £4. 5s. From this must be deducted the fixed charges on the difference in first cost, which we may take at 12 per cent. on £9, or 22s. per horse-power per year, leaving £3. 3s. plus 8s., which will be required for the heating and slashing operations of the mill, or a total of £3. 11s. as the figure at which steam power must be generated to be equal in cost to electric power at £5 per horse-power; and in this figure there must be included the cost of oil, waste, labour, fuel, ash removal, coal handling, superintendence and, most important of all, the item or repairs, which is frequently omitted entirely in making estimates of steam power cost. If it were possible to attain this figure with a steam drive, a power only very inferior to electric drive would have then been obtained.

Production.—Hydroelectric power offers many advantages in operation, due to the readiness with which parts of a mill may be run so that the maximum possible output may be obtained. In equipping a mill for electric drive it is usual to provide one or more motors for each process of the work so that in case the demand on any department is increased, it is possible to work over-time on that particular department; whilst, on account of the inefficiency of the steam engine at light loads and often because of the very small part of its capacity that is required, it would be impossible to run with a steam drive.

In mills using automatic looms they are frequently left in operation at the noon hour, when they will run until some threads break, when the loom automatically stops itself and remains stopped until the weaver returns. Many continue in operation without interruption. In some cases looms are left in operation after shutting down time until the loom stops itself, which often does not occur until all the filling yarn is exhausted. These hours in the aggregate sum up a very respectable total in the course of the year.

The textile industry in the south is at a growing stage and few if any mills are left complete as first installed, especially among the larger mills. In the days before electric power was available this necessitated a steam plant entirely too large for the first installation, so a plan was resorted to of installing one-half of an engine and operating this as a simple engine, with the ultimate intention of adding a cylinder for compounding when the mill should be increased. This arrangement necessitated the investment of a great deal of money in a steam plant, and resulted in very high costs for power when using only a simple engine. With electric drive the system is perfectly flexible. Only the investment for the work actually installed is demanded at the outset, and the full output and efficiency are secured from the beginning.

An interesting application illustrating the flexibility of electric drive has recently been made and is being quite generally followed. In this case a mill was built with a capital of £20,000 and with an equipment of 5,000 spindles for the production of yarns. It was the intention to operate this mill day and night and the promotion of the mill was based on this idea. It was found, however, that for the spinning frames, which require women and girls to operate them, sufficiently satisfactory labour could not be obtained to operate during the night run, so that the management found itself in a position of being able to offer to its stockholders a production based only on the actual money employed, or £20,000. Through their own initiative they then took advantage of the opportunity offered by electric drive and added to their equipment an amount of spinning machinery equal to that already installed. This operated with the rest of the equipment during the day time, and all preparatory machinery, for which only men are employed, is operated day and night, thus giving material to the double number of spinning frames during the day. This resulted in a production equal to that of a mill of 10,000 spindles costing £40,000, while the total cost of the mill was only £24,000. This arrangement has, simply by the proper use of electric power, saved the mill an additional burden of investment of £16,000, the interest and depreciation on which would more than eliminate the entire power bill.

It has been found that in practically every mill that has been converted from mechanical to electric drive, an increase in production has been obtained. This is almost always the case, and it is not usually taken account of by investigators of power costs. Among the uninformed there is a quite general opinion that the converted mill takes to operate it electrically as much as or more power than it previously did with steam. On account of the increased production with the electric drive this is true in a great many cases; but in many other cases it is uncertain, as no accurate records of steam indications have been taken or kept. The explanation of this increase in power is simply that the production has been increased. At the time the motors are installed the speeds of the mill are readjusted and nearly always increased, the power is applied more directly to the work with less chance of slippage of belts and, above all, the speed with the motor drive is much more constant.

The Paper includes 50 curves taken with a delicate recording tachometer, and showing the improved drive with electric motors. In the territory of the larger hydroelectric systems the total number of mills operated consume a large amount of power. Each mill comprised in the group uses a relatively small proportion of the power furnished by the system. It is therefore possible to throw off or on many motors, or, indeed, many of the entire mills without disturbing the speed of the system. This is not the case in a mechanically-driven mill, where even a small part of the machinery represents a good percentage of the total load of the engine.

In a converted mill, driven from a hydroelectric station, one of two results are always brought about. If the original production is maintained the amount of power necessary is reduced. This should not in all cases be regarded as of paramount importance, the most vital advantage being an increased product from the mill, which it has been shown can be obtained through electric drive. This has actually been obtained in nearly every case that has come under my observation. In mills only very roughly converted, where surplus power is taken, and where the old uneconomical arrangement is left intact so that the steam drive may be used when the electric power is temporarily shut off, all carefully kept records show that an increase of production of from 2 to 10 per cent. is obtained. In new mills especially constructed for electric drive the higher of these figures should obtain. This increase is brought about by two things. First, proper balancing of the work, and next, the application of motive power directly to the work it is to drive, and the fact that this motive power has a constant speed value, both instantaneously and continuously.

The importance of production may be shown in a general way as follows: The capital value of a mill's product per annum is about equal to its capital stock. The cost of manufacture, with many variations for the class of work, may be taken proportionately about as follows: Cotton, 60 per cent.; power, 4 per cent; all other costs, 36 per cent.; and the power cost is from 3 to 6 per cent. of the total market value of the product. Thus, assuming the cost of a 5,000 spindle mill as £20,000, its product in a year will be worth, roughly, £20,000 and its power bills, say, £1,000. If the product of this mill could be increased 10 per cent. the gross value of this increase of product would be £2,000, of which the only cost would be cotton and power and some labour. The most costly operations of labour are paid by the day and effect no increase. Allowing, however, for some increased labour cost we have as the total cost of this extra production: Cotton 60 per cent., power 4 per cent., and labour 3 per cent., or a total of 67 per cent., and a net profit of £660 per year, or two-thirds of the total cost of the power, thus nearly eliminating the power bill. On account of the steadiness of the speed of the electric drive the machinery will suffer less deterioration than if run at even lower speeds with the steam drive.

General.—In hydro-electric systems of distribution to cotton mills it is found to be impracticable to place a sub-station for each consumer, especially to meet the conditions which we have in Piedmont, Carolina, where several mills of small or moderate size are installed in one town. This is on account of the large first cost of a sub-station reducing the pressure from 100,000 volts, and also on account of the difficulty of running the high-tension mains through cities and towns. On account of the high cost of transmitting power at low voltage any distance, both as to the initial investment and power loss, it was found necessary to adopt 2,200-volt motors in mills where the general practice had been to use motors of 550, 400 and even as low as 220 volts. At first considerable prejudice existed among the mill owners and the underwriters against the use of high voltage motors, but some years of experience have demonstrated their superiority in every way. The first cost is about equal to that of the lower voltage motors. Their efficiency is equal and the slip is also equal or somewhat less.

In many of the older low voltage installations, for the sake of economy, open wire is run in the mill. The cost of installing it in conduit would be excessive on account of its size. And also on account of the size of the wires, and the very extensive system of feeders, it is only a matter of time until open wiring becomes disarranged, due to its being swept to remove the lint and dirt which it accumulates. Another serious feature of this system is the frequent and necessary employment of fuses to protect smaller branches.

Probably 90 per cent. of the motors burned out in the mills under my charge have been burned out by the failure of one of the three

Digitized by Google

fuses of the three-phase circuit, leaving the motor operating on a single phase. On account of increases to the mill equipment, or bad initial calculations, the wiring loss in the mill often runs up to very high figures with the lower voltages. In one mill in my experience, with a 220-volt distribution about 500 ft. long, the total wiring loss reaches 15 per cent., and this after the mill management had at a considerable cost added feeders from time to time as the mill was enlarged.

In mills using 2,200-volt motors, the wiring is run in iron or steel conduit, and consists of three-wire insulated cables with lead sheaths. The loss in this system is reduced to practically nothing, the cost is low, and complete protection is afforded by means of automatic oil switches. The size of the wires is very small, and the whole system takes up less space in a mill and is no more conspicuous than water and sprinkler pipes. As the conduit is earthed the liability to accident is practically eliminated.

SHOULD THE 1870 TRAMWAYS ACT BE REVISED?*

BY F. COUTTS.

Within the last forty years nothing of public importance and interest has made greater strides than the mode of travelling, and, perhaps, amongst the many varieties of transport, tramways stand out prominent as having undergone the greatest changes and improvements; so much so that the Act of Parliament made in 1870 to guide the laying down and working of street railways, however excellently it may have suited the requirements then, has now become so obsolete as to render it only fit to be included in the list of Parliamentary Acts which have now ceased to serve in a proper way the purpose which led to their being enacted. In addition to the improved methods of conveyance, we must keep in mind that there is a great deal more hustle in daily life now than there was forty years ago, and legislation, like everything else, must be brought up to date, so as to allow business to be carried through and completed in a month's time which forty years ago might reasonably have been held to be quite good enough had it been possible to carry out in three months. It is therefore necessary that the method of obtaining Parliamentary powers to build a tramway be greatly simplified and so save both time and money, and in many cases induce promoters to come forward for powers to construct a tramway in a thinly populated district, who at present, with the heavy expenditure staring them in the face, would never dream of making the attempt.

The period allowed for purchasing, although perhaps ample at the time of the passing of the 1870 Act, with only horse haulage in vogue, and a correspondingly small capital cost to be considered, is much too short for the present system of electric traction, with costly cars, its necessarily heavy and expensive permanent way construction, and overhead and feeders in addition. Although in several instances a longer period than 21 years has been allowed, this has invariably been dearly bought from the local authorities, as in return they have bargained either for money payment or its equivalent. It would, therefore, be well that instead of 21 years, 42 years be substituted, and thus a reasonable time given to the promoters to recoup themselves. Clause 5, which compels promoters to have the support of two-thirds of the local authorities in whose district the proposed route is to be laid, should, without doubt, be cut out, and the same with Clause 9, which prevents a tramway being laid where less than 9 ft. 6 in. intervenes between the footpath and the nearest rail if one-third of the owners or occupiers object. This might well be left to the discretion of the Board of Trade, and thus throw it out of the power of obstinate individuals to compel a tramway undertaking to possibly put in a short stretch of single or interlacing line. But it is not on those points that I wish to dwell so much as those of more interest to us tramway officials who, after powers have been obtained and the lines built, are responsible for the safe and economical working of the systems.

I think some consideration should be given to the question of upkeep. Who should bear the cost of the permanent way repair and renewal? In the horse car days undoubtedly the tram horses were the greatest users of the portion of the highway occupied with the tramway, but now the cars wear nothing but the rails, and considering that tramway owners have been put to the heavy expense of laying substantial track, where in many cases previous to their coming along there were only very indifferent macadam roads, they should be relieved of some portion of the burden of upkeep, for, while tramway owners have steadily been giving additional privileges to the public in the shape of a more frequent service, reduced fares, better roads, &c., those bodies representing the public have given nothing in return, but have been guilty of squeezing the last drop of juice out of the orange wherever an opportunity presented itself, such as charging a price for power entirely outside anything that is reasonable or honest; asking subscriptions to rebuild bridges that on account of the increase in numbers of fast-going vehicles it had become necessary to rebuild, although their building was of no benefit to the tramway company, but rather in some cases to help a motor company running in opposition to the trams, and who use the same roads, but in no way contribute, directly or indirectly, a single penny to their upkeep. Of course, we always hear the old cry from the local authorities, that in face of the tram track being laid, the roads cost them as much as ever to keep up, but we know that this is all humbug, and that although the rate has not been reduced, the money is now spent on other roads; but if the roads of 25 to 30 years ago could be placed side by side with the roads of to-day there would be no comparison, and any large horse contractor could tell that he can, wherever a tramway track is laid, increase his load by at least 25 per cent., and is thus enabled to cut down the charge per ton for carriage on all kinds of material, in this way benefiting, more or less, all ratepayers; and perhaps some such arrangement might be come to as the latter part of Clause 13 of the Tramways (Scotland) Act of 1861 suggests. For while the tramways in this Act were really what we might now term cartways, yet the present tramways fulfil to a large extent the same purpose. The part of the clause referred to reads as follows:—"And the expense of maintaining, managing, and repairing the tramways shall be defrayed by the trustees out of the funds and revenues under their management, or by the person or company by whom the same is laid down, or jointly by the trustees and such person or company, as may be agreed upon."

While criticising the clauses that want to be cut out or recast, there are also a few that might be inserted in the interest of the travelling public's safety, and instead of leaving them to the local authorities, might it not be advantageous to all that they be made compulsory? For instance, all vehicles travelling on roads where tramways are laid to carry lights both front and rear, also that slow-going traffic be compelled, where width of road will permit, to keep clear of tramway track, and so enable, not only tramway cars to travel freely, but other fast traffic.

Should this meeting come to a decision that steps should be taken to have the 1870 Act revised, I would suggest that without further delay a committee be appointed to go very fully into it and bring forward to the Association, with as little delay as possible, a scheme to be followed up to interest the various Members of Parliament into the need for such a change. It will undoubtedly be a stiff job to get it revised, as so many of the local authorities now own their own tramways, and look upon them as a sort of providentially-sent spring to be drawn upon in every conceivable way, to bolster up other less fortunately managed branches of municipal ventures; for although in nearly all cases it would come to the same thing in the end if the ratepayers were taxed to their legitimate amount for the upkeep of the roads, loss on lighting station, &c., and either receive a contribution from the tramways department to the rates or a longer ride for their penny, yet those municipal undertakings must of needs, through sympathy (as was done in the case of compulsory running powers), stand by those municipalities and local authorities who, in many instances, knowing they themselves could not carry out successfully, from various reasons, a tramway scheme to profit, have handed over the concession to some pushing company who are willing to take a sporting risk.

THE "ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. Published annually in February, corrected to mid-February. Established 1882. A very valuable advertising medium, covering the entire Industry. SUBSCRIPTION Price (which is received *in advance* up to Dec. 31st in each year for the next following edition) 8s. 6d. nett, postage 9d. extra. Published price 15s. nett, postage 9d. extra. Postage to British Colonies, 2s. ; Europe, 2s. ; U.S.A., 3s. 6d. ; other countries, 2s. 6d. *Digest of Contents sent free on application.*

THE "G.T." GEOGRAPHICAL DIRECTORY OF THE U.K. (Electrical Section). Subscription 5s., post free.

"THE ELECTRICIAN" PRIMERS (81 Primers in all, and a GLOSSARY). Single Primers 3d. each post free. *New and Enlarged Edition in One Complete Vol. or Three separate Vols. now ready.* FULL PROSPECTUS FREE.

ELECTRIC TRACTION ON RAILWAYS. By Philip Dawson. Price 25s. nett. *Prospectus free.*

ALTERNATING-CURRENT MOTORS. By Dr. Rudolf Goldschmidt. Price 6s. 6d.

THE SHOT-FIRER'S GUIDE: A Practical Manual on Blasting and the Prevention of Blasting Accidents in Mines, Quarries, &c. By W. Maurice. Price 3s. 6d. nett.

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. Wilkinson, M.I.E.E. *New Edition.* Now ready. Price 15s. nett.

ELECTRIC BLASTING APPARATUS AND EXPLOSIVES: With Special Reference to Colliery Practice. By W. Maurice. Price 8s. 6d. nett.

THE ELECTRIC FURNACE IN IRON AND STEEL PRODUCTION. By John B. C. Kershaw, F.I.C. Price 3s. 6d. nett.

BRAKES FOR TRAMWAY CARS. By H. M. Sayers. Price 3s. 6d. nett.

THE MECHANICAL DESIGN AND CONSTRUCTION OF COMMUTATORS. By R. Livingstone. Price 6s. nett.

THE ALTERNATE-CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Prof. J. A. Fleming, M.A., D.Sc., F.R.S. [abroad 13s.

VOL. I.—Price 12s. 6d. post free, abroad 13s. VOL. II.—Price 12s. 6d. post free,

HANDBOOK OF THE ELECTRICAL LABORATORY AND TESTING ROOM. Very fully illustrated. By Dr. J. A. Fleming. Vol. I., 12s. 6d. nett, Vol. II., 14s. nett.

ELECTRIC LAMPS AND ELECTRIC LIGHTING. By Prof. J. A. Fleming. 6s. nett.

ELECTRICAL LABORATORY NOTES AND FORMS. Arranged by Dr. J. A. Fleming, M.A., F.R.S. Single copies 4d. nett, or in dozens at 3s. 6d. nett. Complete Sets of 50 Notes and Forms, 12s. 6d. nett, or in strong portfolio, 14s. nett ; or bound in strong cloth, 15s. nett. Spare Copies of Tabular Sheets, 1s. per dozen. Portfolios, 1s. 6d. each. Sectional paper, 1s. per dozen sheets. *Complete Prospectus post free on request.*

A SMALLER SET of only 40 Forms, bound strong cloth. Price 7s. 6d. nett.

CENTENARY OF THE ELECTRIC CURRENT—1799-1899. By Prof. J. A. Fleming, F.R.S. Price 1s. ; strong cloth 2s. 6d.

ELECTRICITY METERS: THEIR CONSTRUCTION AND MANAGEMENT. By C. H. W. Gerhardi. Profusely illustrated. Price 9s. nett.

ELECTRICITY IN HORTICULTURE. By Prof. S. Lemstrom. Illustrated. 3s. 6d. nett.

RADIO-ACTIVITY: AN ELEMENTARY TREATISE, FROM THE STANDPOINT OF THE DISINTEGRATION THEORY. By Fredk. Soddy, M.A. Fully illustrated. Price 6s. 6d. nett.

ELECTROMAGNETIC THEORY. By Oliver Heaviside. Vol. I. Price 12s. 6d. Vol. II. Price 12s. 6d. *Vol. III. in the press.*

MOTIVE POWER AND GEARING FOR ELECTRICAL MACHINERY. By E. Tremlett Carter, C.E., M.I.E.E. Revised by G. Thomas-Davies, A.M.I.E.E., F.C.S. Price 12s. 6d. nett.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. Ewing, B.Sc., F.R.S., F.R.S.E. Price 10s. 6d.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. Kennelly and H. D. Wilkinson, M.I.E.E. Price 6s. 6d.

ELECTRIC MOTIVE POWER. By Albion T. Snell. Price 10s. 6d. nett.

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. Geipel and H. M. Kilgour. Price 7s. 6d. nett.

ELECTRICAL TESTING FOR TELEGRAPH ENGINEERS. By J. Elton Young. Price 10s. 6d.

STUDENTS' GUIDE TO SUBMARINE CABLE TESTING. By H. K. C. Fisher and J. C. H. Darby. Price 7s. 6d. nett.

SIGNALLING ACROSS SPACE WITHOUT WIRES: THE WORK OF HERTZ AND HIS SUCCESSORS. With new Chapter on Tuning. By Dr. Sir Oliver J. Lodge. Price 5s. nett.

THE ART OF ELECTROLYTIC SEPARATION OF METALS. By Dr. G. Gore, LL.D., F.R.S. Price 10s. 6d.

ELECTRO-CHEMISTRY. By Dr. George Gore. Price 2s.

BEGINNER'S MANUAL OF SUBMARINE CABLE TESTING AND WORKING. By G. M. Baines. Price 7s. 6d. nett.

CARBON MAKING FOR ALL ELECTRICAL PURPOSES. By Francis Jehl. Price 10s. 6d.

THE ELECTRICIAN" WIREMAN'S POCKET BOOK. Edited by F. C. Raphael. Price 5s. nett.

"THE ELECTRICIAN" HANDY WIRE TABLES FOR THE POCKET. By P. B. Down, Wh.Ex., A.M.I.Mech.E. Price 2s. 6d. nett.

THE RATING OF ELECTRIC LIGHTING, ELECTRIC TRAMWAY, AND SIMILAR UNDERTAKINGS. By W. G. Bond, M.I.E.E. Price 2s. 6d. nett.

DRUM ARMATURE WINDING AND COMMUTATORS. By F. M. Weymouth. 7s. 6d.

PRIMARY BATTERIES: THEIR CONSTRUCTION AND MANUFACTURE. By W. R. Cooper. Price 10s. 6d. nett.

SECONDARY BATTERIES: THEIR CONSTRUCTION AND MANUFACTURE. By E. J. Wade. Price 10s. 6d. nett.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. Price 1s. 6d.

THE LOCALISATION OF FAULTS IN ELECTRIC LIGHT CABLES. By F. C. Raphael. 7s. 6d.

THE STEAM-ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. Beaumont, M.I.C.E., M.I.M.E., &c. Price 6s. nett.

THE ELECTRIC ARC. By Mrs. Ayrton, M.I.E.E. Price 12s. 6d.

TRAMWAY TRACTIVE EFFORT AND POWER DIAGRAM. By Arnold G. Hansard, B.A., A.M.I.E.E. Price 4s. 6d. nett ; in Tube, 5s.

THE BRITISH POST OFFICE TELEPHONE SERVICE. Fully illustrated.. Price 3s. 6d. nett.

INTERNATIONAL TELEGRAPH CONVENTION AND SERVICE REGULATIONS. Price 6s. nett. (LISBON REVISION, 1908.)

BOILER FEED WATER. By F. W. Anderson. Price 6s. nett.

(PRELIMINARY) WIRELESS TELEGRAPH CONFERENCE (BERLIN, 1903), PROCEEDINGS AT. Price 8s. 6d. nett.

INTERNATIONAL WIRELESS TELEGRAPH CONVENTION AND SERVICE REGULATIONS (BERLIN, 1906). With complete report of Proceedings. Price 21s. nett.

THE CLASSIFICATION OF ALTERNATE-CURRENT MOTORS. By V. A. A. Fynn, M.I.E.E. Price 3s. nett.

ELECTRIC CRANES AND HOISTS. By H. H. Broughton. *In Preparation.*

PRACTICAL TELEPHONY. By W. Aitken, M.I.E.E. *In Preparation.*

ELECTRIC MAINS AND DISTRIBUTING SYSTEMS. By J. R. Dick, B.Sc., and F. Fernie, A.M.Inst.C.E. *In Preparation.*

THE PRACTICAL WIRELESS SLIDE RULE. By Dr. H. R. Belcher-Hickman. Price 2s. 6d. nett. *Nearly Ready.*

THE MECHANICAL DESIGN AND CONSTRUCTION OF GENERATORS. By R. Livingstone. *In Preparation.*

LIGHT, RADIATION AND ILLUMINATION. From the German of Paul Högner, by Justus Eck. *In Preparation.*

The Electrician.

The Oldest Electrical Journal (established as a weekly Journal, 1861-1878).

Published every Friday, Price Sixpence; Post Free, Sixpence-Halfpenny.

Editorial, Publishing and Printing Offices,

1, 2 & 3, SALISBURY COURT, FLEET ST., LONDON

"THE ELECTRICIAN" INDUSTRIAL SUPPLEMENT.

With "THE ELECTRICIAN" for Sept. 14, 1906, was issued the first of a series of "Industrial Supplements," to be published from time to time with "THE ELECTRICIAN." The fifty-first issue of the Supplement will be published (Gratis) with the next number of "THE ELECTRICIAN."

The "INDUSTRIAL SUPPLEMENT" is a comprehensive record of developments in Electrical Plant, Machinery, Apparatus, Accessories, Sundries and Materials, and of their proved suitability for various Industrial purposes.

The "INDUSTRIAL SUPPLEMENT" is holed for filing or hanging, and filing covers can be supplied for holding 6 or 12 issues.

SPECIAL NOTICE.

NOW READY.—Vol. LXIV. of "THE ELECTRICIAN" (1,035 pages) bound in strong cloth. Price 17s. 6d.; post free, 18s. 6d. Now ready. Cases for Binding. Price 2s.; post free, 2s. 3d.

A complete set of "THE ELECTRICIAN" can be supplied. A number of odd volumes and some odd old back numbers, to help in making up complete sets, are also available.

SAFETY IN TRAIN LIGHTING.

Train lighting is one of those specialised subjects that do not receive much attention in the technical world. This is rather to be expected, for the field of train illumination is so very much smaller than that of public electricity supply for light and power. Nevertheless the subject is important, and we may certainly say that to the travelling public it is very important indeed.

First, there is the question of adequate and steady illumination. Not so very many years ago railway travelling after dusk was a most monotonous procedure, as reading was only possible at considerable risk of damaging the eyesight. Since those days there has been a very marked change for the better, and passengers can now read with comparative comfort. There is, however, a further point which we wish to emphasise more particularly on the present occasion, namely, that of safety. In raising this question we have no wish to be in any sense alarmist. Considering the vast number of train miles run every year it will be admitted that railway travelling is now extraordinarily safe. Nevertheless, so long as the human element is present in railway working, accidents certainly will occur from time to time, and in such cases it is most important that the illuminant should be of such a character as not to give rise to fire. A

Digitized by Google

railway accident in itself is bad enough, but the horror is increased tenfold if a fire occurs.

In this connection it can be said, without fear of contradiction, that electricity is very much ahead of its rivals, and that it is in fact the only safe illuminant. This point is being much more fully appreciated on the Continent than in this country. Thus, in a recent issue of the "Neue Freie Presse" of Vienna, it is pointed out that a number of railway accidents have taken place recently at Marburg, Herlishein, Trenton, Missouri, Uhersko, on the Canadian Pacific Railway and elsewhere, and that in such cases, as a sequel to the accident, the gas used for illumination has caused a fire to break out, thus sacrificing the lives of passengers who would otherwise have escaped. At a meeting of the Council of the Austrian State Railways recently the Ministry were requested to introduce a modern illuminant for lighting railway stock, and the representatives of the Administration informed the meeting that it was their intention to introduce incandescent gas lighting. At the next meeting this decision led Mr. MAXIME KRASSNY to move the following resolution :—"The Ministry for Railways is requested to discontinue the use of gas for lighting passenger trains, and to use exclusively electric lighting for all future passenger cars as well as for those at present on order."

In the discussion that ensued Dr. ELLENBEGEN mentioned that in Italy gas was being completely eliminated, even oil being used in preference. There were still approximately 1,400 cars lighted with gas on the Italian railways, but a portion of these were being converted to electric lighting, and the others were to be converted in the near future. The representative of the Government, in replying, stated that the Administration were doing everything in their power to improve the lighting, having regard to the means at their disposal. A series of tests which had lately been completed showed that, taking into consideration recent improvements, electric train lighting possessed economical advantages. As a result of these tests they had decided not only to convert old cars to the electric system, but that the same system should be used for the new cars to be supplied in 1911 ; and if further results were in any way favourable to electric lighting the use of this system would be greatly extended in future. As a result of the discussion a resolution was adopted practically in the form moved by Mr. KRASSNY.

In all such matters, of course, the question of cost is of some importance, but where safety is concerned cost should not be permitted to have an undue influence. In the present case, however, there is not much to choose between the cost of running electric light and incandescent gas for train lighting. The introduction of the metal filament lamp has, naturally, placed the electrical method at some further advantage, though it is rather in the improvement of the illumination than in the reduction of the running cost. In electric train lighting equipments the running cost is largely due to the initial outlay. The cost of producing the energy is negligible, and therefore it does not matter whether the lamps are efficient or inefficient. On the other hand, with metal filament lamps the battery can be smaller than would otherwise be the case, and consequently there is a gain in part of the equipment, and there is a marked advantage in the better illumination that can be given. In any case, the difference in cost between the two systems appears to be comparatively small, and therefore there is every reason for train lighting to be considered from the point of view of safety in this country as on the Continent, and that without delay. Questions involving the safety of the general public on railways come under the control of the Board of Trade, and, considering the present position of the whole question, we do not think it would be out of place for the Board of Trade to take some action in the matter without waiting for a disaster, with its attendant sacrifice of human life, when public opinion will doubtless force such action to be taken.

REVIEWS.

(Copies of the undermentioned works can be had from THE ELECTRICIAN Office, post free, on receipt of published price, adding 3d. for books published under 2s. And 10 per cent. for abroad or for foreign books.)

Electricity. By H. M. HOBART. (London : Constable & Co.) Pp. xix. + 207. 6s. net.

Mr. Hobart's latest contribution to electrical literature would, in the ordinary course of events, be exceedingly difficult to review. But, happily, the task is somewhat lightened by the author's habit of providing a preface in which, besides discoursing on things in general, he tells us his reasons for writing the book and the methods by which he hopes to carry out his ideas. Having read the preface, we know what we ought to expect, and having been introduced to the ideal in the preface are able, in its light, to criticise the reality.

Mr. Hobart's wishes in the teaching of elementary electricity, or rather electrical engineering, to break away from old methods and to produce a book in which "friction machines, electric eels, frog's legs, pith balls, lodestones, sealing wax, cats' skins, the electrophorus, the aurora borealis, St. Elmo's fire and Benjamin Franklin's kite" are omitted as being "rarely of importance to the present generation of students of electrical engineering." It is a worthy conception, and one which, if fully carried out, should do much towards the cleansing of elementary electrical engineering from the barnacles now too closely clinging to it, always provided that general knowledge is not too much curtailed.

Turning to detail, we are met by the difficulty that we cannot view the first few chapters through the glasses of those for whom they are primarily intended. Mr. Hobart would, in fact, be well advised to get some first year Finsbury student to give his opinion on the question; it would be more useful, in some respects, than ours.

Our first criticism is, starting at the beginning, on the title. It is too wide ; for the book is certainly not essentially on, or mainly about, electricity, as the term is generally understood, but is rather devoted to electrical engineering matters. Though Mr. Hobart tells us that the word "electricity" is commonly used when "electrical energy" is meant and that he has followed usage, yet since this book is presumably intended for budding electrical engineers, it would have been better to have been more guarded in his nomenclature. The eradication of good habits and the acquirement of bad are both too easy.

Again, Mr. Hobart, as a necessary consequence of his nomenclature, refers to the B.T.U. as a measure of the quantity of electricity. Of course, Mr. Hobart does not mean anything of the kind, but this unnecessary looseness of expression on the part of the teacher will inevitably lead to looseness of thought on the part of the student. Such looseness of thought is already too rife among electrical engineers, as is evident by

Digitized by Google

the frequency with which one sees such expressions as "steam consumption per kilowatt."

Mr. Hobart continues to urge the claims of the "kelvin," that is, the kilowatt-hour. There is certainly much to be said in favour of reducing electrical, thermal and other energy calculations to such a quantity, but we are a little doubtful if the nomenclature will be generally adopted. Names are convenient, but they give us more to remember; whereas a term, such as "kw. hr.," of which the meaning is self-evident, has a great advantage. The term "B.T.U." is also available, but doubtless seems far removed from mechanics. There is much less reason for the adoption of the name "siemens" (which will remind older readers of resistance) to denote the watt hour.

Mr. Hobart, like most authors, is fond of his own ideas, and perhaps this accounts for some rather odd minor details. It is a well known rule in literature that an abbreviated word is followed by a full stop. This is more or less rational and certainly convenient. In the book before us this rule has been brushed on one side, and thus we have such expressions as ats (ampere turns) per cm length, and rings of 4 sq cm cross-section with a one mm airgap and flux measured in cgs units. In this country decimal points are indicated by stops and multiples of thousands by commas, whereas on the Continent decimal points are always indicated by commas. Each method may be equally good in its place, but we fail to see why Mr. Hobart should adopt Continental practice in this respect any more than Continental writers should adopt our method. Thus "1 000 000 grams" has an odd appearance, and to be told that the specific heat of water is 1,044 at 200 deg. is risky for the elementary student. Surely the aim of an author should be to make the reading of his book easy, not confusing.

The book, as it stands, may be divided, and indeed falls naturally, for critical purposes into two portions; in the first of these the author deals with elementary questions including conductors, energy, Ohm's law and the magnetic field, and is in parts rather laboured. The chapter on the magnetic field deals with fields due to currents, and goes minutely into the variation of the strength of field as the distance from the conductor or conductors is varied. What may be described as the second part of the book deals with conductors moving in a magnetic field, "alternating electricity," inductance, the magnetic circuit and insulating materials. Here there is much that will repay study, though, since anything mathematical is taken for granted, the treatment is often "sketchy," more particularly in alternating currents. Naturally, this remark does not apply to such a subject as insulating materials, of which a very good account is given in brief.

We cannot really recommend the first part of the book, in spite of the many excellent curves and useful tables which are contained therein. The author's argument in working up to his conclusions is not close enough for the elementary student, and the introduction of practical details about metal filament lamps, for instance, is not, we think, very wise. The second part of the book, however, forms an excellent introduction to the study of electrical design. The argument is not hurried, and the reason for many operations which are decidedly obscure to most students is well explained.

The most valuable feature of the book is that the point of view is very different from that of the ordinary text book. Thus the magnetic field due to currents is dealt with graphically and arithmetically in detail. But, as much is taken for granted, we think it is rather a book for the teacher than for the average student. The average teacher would benefit, because it would enable him to put things differently from the stereotyped method, and the matter could then be administered discreetly with much advantage.

Electrical Installations of Electric Light, Power, Traction and Industrial Electrical Machinery. By RANKIN KENNEDY. Vol. III. (London: The Caxton Publishing Co.) Pp. 244. 7s. 6d. net.

Vol. III. of this work is devoted to Gearing, Turbines, Steam, Gas and Oil Engines, Switchboard Wiring and Accessories. The portion on Gearing is simple and practical as regards belts and couplings, but might with advantage have dealt more fully with toothed and worm gearing, which is now of much greater importance in connection with electrical work. Turning to motive power, the preliminary remarks are useful, and include an exposure of the fallacy of the proposals for liquid air as a motive agent. Wind and water turbines are briefly dealt with, and steam turbines fairly fully, the De Laval, Parsons and Zoelly forms being described, but not the Curtis type. Of high-speed steam engines the Willans, Westinghouse, Belliss and Mather & Platt engines are considered, but the author is of the opinion that the days of such engines are numbered. Gas and oil engines receive a considerable amount of attention, as the author thinks that "the next generation of engineers in all likelihood will abandon steam in electrical generating altogether." He tells us little, however, as to the reliability of gas and oil engines and of producers, nor does he warn us of the restricted sources and control of the oil supply.

Among the general remarks which the author is fond of sandwiching in between his technical descriptions are some sensible ones about the importance of the thorough mechanical training of the electrical engineer, especially as regards engines. We may also agree with his remark that "the great mistake in our technical schools is the attempt to teach too much, giving a very scanty training in many subjects, instead of a thorough training in a few correlated subjects," except that we would rather say that the fault lies in cramming students with descriptive knowledge of details rather than teaching them the essentials and principles by which they can readily realise the action of any actual machine and evolve improvements themselves. It is the examination and syllabus system which is chiefly responsible for this. The sections dealing with Motor Wiring and Switchboards call for little comment; but wiring might have been more fully dealt with, notably as regards fittings and Continental wiring. A brief description of mining machinery closes the volume. The frontispiece is a dissected diagram of the author's form of salient pole two-phase motor.

IMPROVING THE PORTABILITY OF THE WESTON NORMAL CELL.

BY HENRY TINSLEY.

One of the greatest difficulties experienced in making standard cadmium cells for commercial use is that of making them sufficiently robust, so that the chemicals do not become displaced during transit to the customer or when being sent to and from the standardising laboratory. This is of special importance in the case of cells which are destined for a tropical country, as in this case the risk of disturbance is very much increased by the heat and inevitable jarring during transit.

The recommendation of the National Physical Laboratory to ensure that the chemicals shall retain their proper respective positions is to crystalise some of the cadmium sulphate solution so as to form a crystalline plug after the cell has been set up. This crystalline plug is so arranged as to form just below the constriction shown in Fig. 1, the constriction acting as a further safeguard by preventing the plug sliding up or down the tube.

The writer has made hundreds of cells of this type and despatched to different parts of the world, including places as far away as China and South America, and apparently such cells arrive in good condition.

Special care has, however, to be taken in forming the crystalline plug for cells that have to go to hot climates; usually it has to be made very thick so that the solution of the crystals at the higher temperature abroad will not be sufficient to allow the plug to shift or the crystals to separate and crumble. A further disadvantage is that the thicker plug considerably increases the internal resistance of the cell, and though this may ultimately fall to about the right resistance, it is an uncertain factor and as such should be avoided if possible.

The writer has tried many ways of overcoming this diffi-

Digitized by Google

culty by placing a mechanical plug over the solid chemicals, such as perforated discs of mica and porcelain, a plug of glass wool, asbestos pads, &c., none of which appear quite so satisfactory as the method described below :—

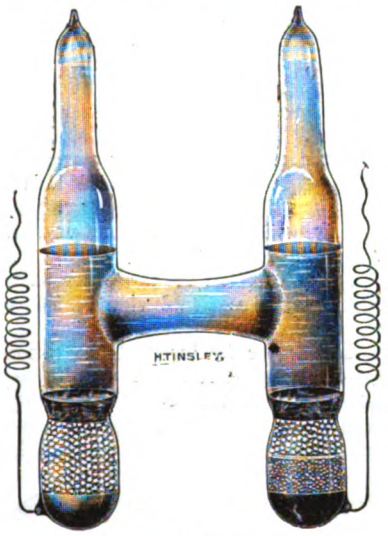
The essentials of such a screen or plug are that :

1. It must not introduce any deleterious matter into the cell, such as may cause the cell to change.

2. It must not increase the internal resistance of the cell appreciably.

3. It must be strong enough to be placed firmly in position and hold the heavy chemicals securely against sudden jars.

When the separate limbs have been filled with their amalgam, mercury and respective chemicals, small rings of cork are made tightly fitting the inside of the glass limbs, the centre hole of these rings being kept as large as possible. Some pure unbleached linen is now carefully freed from its dressing by washing and boiling till no sign of chemical matter can be detected. This is then dried and cut into discs, the same size as the outside diameter of the rings. These discs are then sewn to the bottom of the cork rings, forming miniature drumheads which can be inserted as plugs on the surface of the layered chemicals. These drumheads are now forced firmly on the solid matter and will hold the chemicals in position against even violent handling. In a tropical climate, however, some solid crystals of $CdSO_4$ are sure to be taken up in solution, and the chemicals in the drumhead may become loose, so that it is as well to add a few crystals of $CdSO_4$ *above* it to allow for this.



PORTABLE WESTON CELL.

The constriction in the glass limbs is retained as in the N.P.L. pattern cell, as this acts as a guide to the height of the chemicals, also being an advantage for binding the platinum wires against slipping during the mounting and manufacture of the cell.

Cells set up in this way do not appear to be materially affected in the E.M.F. by the linen screen, and as this at once becomes impregnated with solution, its resistance is kept low, the linen only being very thin, much thinner than a glass wool or asbestos plug would be, besides affording a fairly free passage for solution as the limbs of the cell expand or contract.

The table given below will clearly show how much more uniform in internal resistance cells made in this way are, besides having the great advantage of allowing immediate sealing after construction and a simpler form of tube being used.

New type of cells with diaphragm.			Cells with constriction and crystal plug.		
No. of cell.	Volts.	Internal resistance.	No. of cell.	Volts.	Internal resistance.

THE BRUSSELS INTERNATIONAL EXHIBITION.—IV.

THE ELECTRICAL AND ENGINEERING EXHIBITS.

The French electric motor makers appear to be keenly alive to the importance of the individual drive for practically every class of industrial machinery. In the International Machinery Hall will be found numerous interesting examples of the electric drive in the textile trades. Messrs. H. Duesberg, of Bossons, exhibit a number of cotton carding engines, each gear driven from 2 H.P. continuous-current motors. They also show several examples of opening machines, each operated by its own motor. The Panhard Levassor Co. show a large band saw operated by a 60 H.P. continuous-current motor which is placed below the floor level and which is connected to the machine by belts. In the French industrial section, which is reached from the machinery hall by ascending a staircase, are the exhibits of the principal electrical manufacturing firms. The Société Alsacienne Belfort make a good show of three-phase turbo-generators and a quantity of typical motor-operated mining machinery. On the stand of the General Electric Co., of Nancy, is an interesting 12,000 volt solenoid operated switch capable of dealing with 5,000 kw. Messrs. Berthoud Borel, of Lyons, exhibit specimens of high-tension and extra-high-tension cables and also X-ray apparatus. The Société Ateliers de Construction du Nord, of Jumet, show specimens of generating plant and controlling apparatus employed on a 150,000 H.P. high-tension plant. In the section devoted to the metal exhibits are to be seen many fine examples of French steel work. The Société des Acieries de Longwy, amongst a quantity of steel products, exhibit the steel frame of a 16-pole direct-current dynamo, which weighs 16 tons. Messrs. Paul Girod also show a 9 ton field frame, 14 ft. 6 in. internal diameter. In the same section may be seen a number of useful products of the electric furnace, particularly of the Héroult furnace, in which examples of aluminium in practically every conceivable form are shown. A particularly interesting item on this stand is a tank some 8 ft. in diameter by 5 ft. 6 in. deep, made up of welded aluminium plate. Adjoining this exhibit is an interesting model of the Rhone Valley hydro-electric plant, which has a capacity of 330,000 H.P., and operates under a 220 ft. fall. The model shows the situation of the dam at an extremely rugged portion of the valley and it also shows the location of the forebay, draught tubes and tail race. Immediately surmounting the crest of the steep side of the valley is a large transformer house where the pressure is raised for the transmission line. Just above the model is a large wall map of France on which are shown the positions of the principal generating and sub-stations of the company operating this extensive system. The principal transmission line is one of 72 miles from Grenoble to the steel centres at St. Etienne. The company has in view a scheme for the transmission of energy from Grenoble to Paris, but up to the present time nothing further has been done towards carrying this project into operation.

The Belgian exhibits of electrical apparatus include a 125,000 volt transformer plant of the Société de Constructions Electrique de Charleroi. The same company also exhibit specimens of suspended insulators for extra high tension and special line work. This exhibit is placed in the Belgian Industrial Hall and immediately adjoins the principal British section.

There is a good show of German machine tools, all of which are electrically operated, and the cranes which span the main machinery exhibit are of considerable interest, particularly one by Messrs. Stuckenholtz, which has been designed specially for use in steel works for lifting steel ingots out of the soaking pits. Actual examples of these pits have been installed on the stand and the crane is shown at different times of the day lifting weights up to 20 tons. The exhibits of lighter electrical apparatus in the German section include a good display of insulators, both for ordinary electrical work and also for extra high voltage transmission lines by the Hermsdorf Porcelain Works.

In the British section of the Exhibition there is no moving machinery shown, but the textile industries occupy a large proportion of the space with attractive displays of cotton and woollen goods. They take the shape of tableaux arranged in a darkened portion of the building, which is effectively lighted by electric lamps. These tableaux form one of the most interesting and attractive sections of the British exhibit. The Bradford Chamber of Commerce have got together a series which depict the stages of manufacture of woollen goods from the raw material to the finished product. The tableaux illustrating mechanical processes have been carefully prepared, and they show wool combing, spinning, weaving and dyeing. An illustration of the wool combing tableaux is shown in Fig. 1. The setting is made up of a couple of circular wool combing machines which are connected by belt to an overhead shafting. In the illustration it will be noticed that the effect of the interior of the wool combing

Digitized by Google

shed is given, but this has been obtained by the use of a suitable background. The two figures in the foreground are wax, and the other figures are painted on the background. The machines themselves are of a slightly smaller pattern than those used in a woollen mill, but they are of a type which is now extensively operated by electricity in Bradford and the surrounding district. But for the fact that there was no motive power circuit laid into the British section we understand that these interesting machines would have been shown in operation. Engineers visiting the Exhibition who are

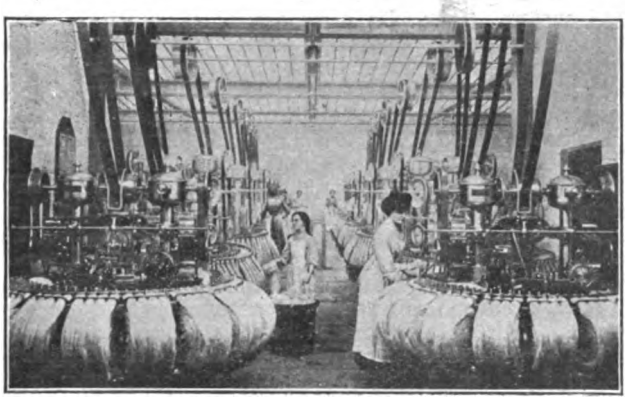

Fig. 1.—One of the Tableaux in the British Section showing the Wool Combing Process as employed in the Bradford Woollen Mills.

not familiar with the various processes of wool preparation should make a point of seeing these tableaux.

An interesting British exhibit in the Industrial Machinery Hall is that of the Underfeed Stoker Co., who are showing their class B and class E type stokers on stand No. M.54. In addition, they have one of their air heaters on view, this device having been developed for heating the air supplied in the furnaces of either water-tube or Lancashire boilers. Fig. 2 shows the application of this heater to a standard Babcock & Wilcox boiler. The heater itself is made up of a number of semi-circular flat units, which are placed horizontally or vertically in the main flue of the boiler. The hot gases pass between these units and raise the plates to a high temperature. There is an enclosed space or tunnel left between each plate to admit of the passage of air, and this is drawn or forced in by means of a fan. It will be seen from the illustration that the heater can be conveniently placed at a point where the hot gases from the grate, after passing through the boiler tubes, impinge on the heater discs. The fan forces the air through the heater round suitable ducts to the grate at the front of the boiler. The heater can be supplied to a single boiler, or a large pattern heater can be inserted in the main flue, and air can be delivered from this to a whole battery of boilers.

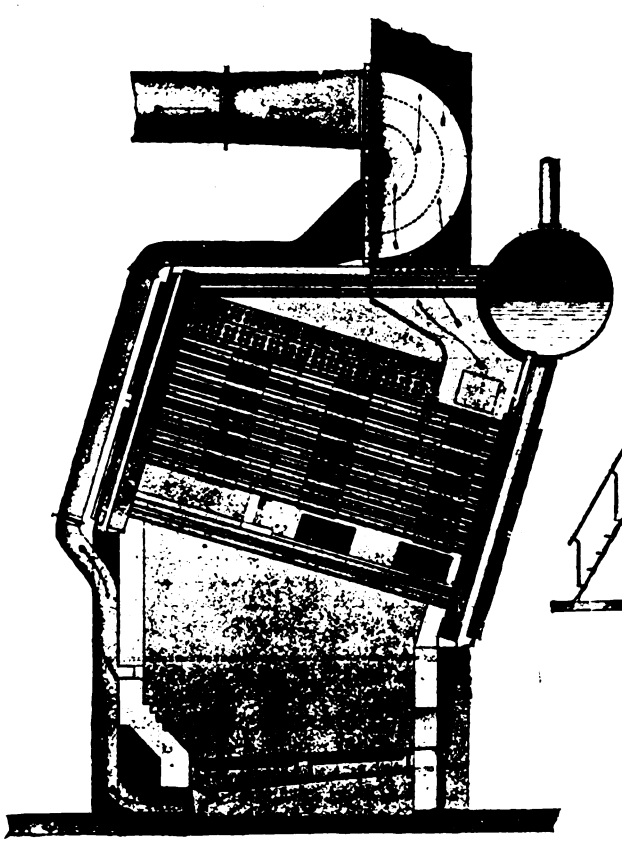

Fig. 2.—General View of Air Heater applied to Babcock Boilers.

In the German section Messrs. R. Wolf make two distinct exhibits

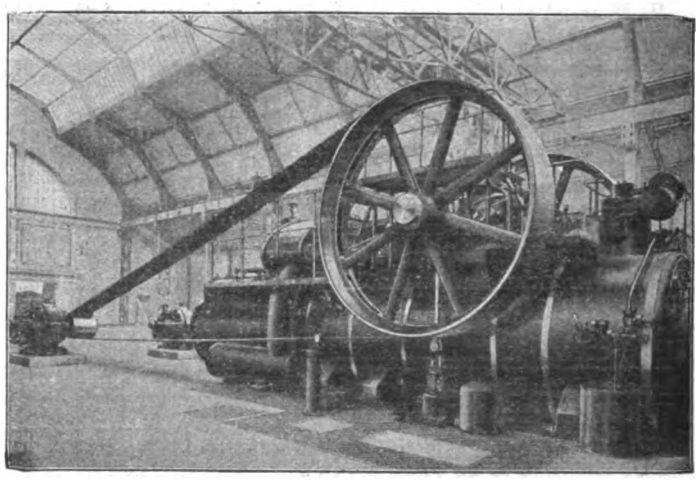

Fig. 3.—650 h.p. Wolf Locomobile in Power House of the German Section.

of their well-known locomobile. One is in the Machinery Hall, and comprises a 100 h.p. compound condensing h.p. locomobile, a 15 h.p. high-pressure locomobile and a portable locomobile. This exhibit has been made to attract attention to the value of the Wolf locomobile for agricultural work or similar service where a temporary power plant is required. Several patterns of agricultural machinery are introduced into the exhibit, including centrifugal and plunger type pumps. The second portion of the exhibit is in the power house adjoining the Machinery Hall, where a 650 h.p. Wolf locomobile is in daily operation driving two 200 kw. direct-current generators by belt from the main flywheels. Fig. 3 is a general view of this exhibit taken previous to the erection of the other units in the power house. Fig. 4 illustrates a sectional view of this particular locomobile, and an inspection of this will make clear the position of the superheater, the feed water heater and the automatic sprinkler stoker. The locomobile runs at 170 revs. per min., and each dynamo is driven by an 18 in. belt. We have dealt very fully with the Wolf locomobile in previous issues, but we may recall here the remarkable efficiency of these self-contained steam plants. Recent tests by

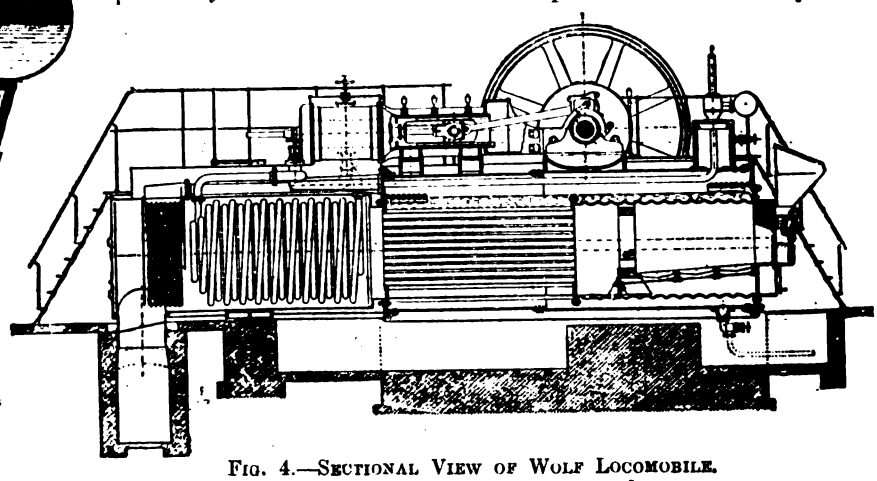

Fig. 4.—Sectional View of Wolf Locomobile.

Prof. Burstall on a 150 h.p. locomobile showed a steam consumption of 8·81 lb. per brake horse-power-hour, and a coal consumption of 1·05 lb. per brake horse-power-hour. These figures are exceptional, and illustrate the amount of care taken in the design and construction of these machines. It is interesting to recall the fact that the 650 h.p. plant in the power house of the German section was in position and running some month or six weeks before the exhibition was due to open, and various exhibitors could therefore be supplied with light and power. In a pamphlet issued by the company it is stated that there are 3,000 men employed at their Magdeburg works, and that upwards of 4,000 superheated locomobiles have been built with an aggregate horse-power of 350,000.

CORRESPONDENCE.

STREET LIGHTING CONTRACTS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your issue of July 8th you reprint a Paper in which Mr. Jacques Abady deals with the above subject and, in particular, gives his reasons for advocating a specification based upon the light emitted, rather than upon the energy consumed, by the lamps installed. That this proposal is a distinct step in the right direction will, I think, be admitted by all who have studied the question, and the Westminster City Council are to be congratulated upon having issued their recent lighting specification upon this basis.

Whether, however, the particular specification proposed by Mr. Abady is altogether satisfactory seems open to doubt. As regards the adoption of candle-power, instead of illumination, as the basis of comparison, I am inclined to agree with the author, in that the former is undoubtedly better understood by the lay mind and, for this reason, to be preferred in a case of this kind. At the same time I cannot agree with Mr. Abady when he speaks of illumination measurements as introducing "all kinds of difficulties and problems (as to the behaviour of light rays with respect to surfaces and view point) about which photometrists themselves are not agreed." This might have been the case 10 or even five years ago, but is certainly not so to-day. The author appears further to have overlooked the fact that the illumination in foot-candles is what is actually measured by all forms of photometer, and that the candle-power has to be subsequently *calculated* from this.

In this connection I notice that the photometer is specified to be one "working on the law of inverse squares." What this clause is intended to convey does not seem at all clear, unless it is that the adjustment of illumination is to be made by sliding the standard lamp to and fro until balance has been obtained. I hardly think however, that this can be the intention, seeing that this particular method of adjustment has been abandoned in nearly all modern photometers intended for street work.

Probably the most important, and in my opinion the least satisfactory, part of Mr. Abady's proposal is the definition of the candle-power called for as the mean of two measurements at 20 deg. and 50 deg. respectively with the horizontal. The author points out that the aim in the design of a street lamp should be to provide a maximum of light at angles of 10 deg. or 20 deg. with the horizontal and a *minimum* below 40 deg. By assigning equal importance to the candle-power at 50 deg. and at 20 deg. (as is the case with the proposed specification) encouragement is given to a distribution of light which is distinctly bad from the street lighting point of view.

To overcome this very serious drawback I would venture to suggest that, instead of angles of 20 deg. and 50 deg. with the horizontal, 15 deg. and 25 deg. should be selected. Or, if it was feared that such a proposal might lead to the entire neglect of the illumination near the vertical (which I do not for a moment think likely), the 20 deg. rays might be given a preponderating influence on the result by adding the candle-power of the 50 deg. ray to that of the 20 deg. ray doubled or even trebled and taking the mean.

A comparison of polar curves 11 and 13 in Mr. Abady's Paper illustrates, I think, the unsatisfactory nature of his proposed definition of candle-power. The former is cited by the author as "a bad example" of light distribution and the latter as a particularly good one, and yet, judged by their 20 deg. and 50 deg. ordinates, the "bad example" is quite as good, if not better than, the other.

It seems a little doubtful whether it can be regarded as satisfactory to take any arbitrary angles, owing to the fact that, at some points, the polar curve of light distribution is so steep that a small change in the angle makes a very serious difference in the candle-power. This is well seen in Mr. Abady's digaram No. 12 (10-ampere flame arc) in which, at 20 deg. with the horizontal, an error of only ± 4 deg. in the measurement of the angle makes a difference of nearly 50 per cent. in the candle-power.

There is one other matter to which I should like to allude, as it seems so far to have escaped attention, and that is as to how far it is possible to speak of the "candle-power" of a lamp fitted in a dioptric lantern or provided with a curved reflector.

The whole notion of candle-power is bound up with the conception of the light emanating from a point, and consequently obeying the law of inverse squares. That this law is quite inapplicable to lamps provided with lenses or mirrors will be at once obvious if the extreme case of a parabolic mirror, such as that fitted to a searchlight or to an acetylene motor headlight, be considered.

To speak of the "candle-power" of such a lamp would be quite meaningless, and all that could be said would be that at a given distance from it a certain illumination was produced. I have not personally carried out any tests in this direction, and it would be interesting to inquire how far such considerations applied to some of the modern street lanterns.—I am, &c.,

Westminster, July 11. KENELM EDGCUMBE.

THE CRADLE DYNAMOMETER.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The article by Messrs. Davies and Shaw in your issue of this morning is of considerable interest, and I am glad to see that the cradle method, which, in my opinion, is by far the best of all the devices for the measurement of power, hitherto designed, is again brought into prominence. As, however, the authors refer somewhat specially to my own form of what I call a regenerative dynamometer brake, perhaps you will permit me to deal with some of their criticisms.

The mounting of the machine under test upon a cradle, instead of direct coupling it to a permanently suspended machine, as in my own form, was carefully considered by me before adopting the latter arrangement, and rejected for two principal reasons, one being that the mounting of every fresh machine meant jarring the suspension, and the other that unless the axis of the machine under test coincided exactly with that of suspension, any resultant side pull due to the driving belt or other cause would be a cause of error. In brief, the mounting of a machine on a cradle to obtain the best results require a number of adjustments which are much better done once for all upon a machine kept for the purpose, than repeated at every fresh test with machines of different sizes, weights, &c. Coming next to the question of knife edges *v.* ball bearings, my brake was originally tried with the latter, and found to be insufficiently sensitive. It must be remembered that the generator was a heavy machine of 8 kw. capacity. The addition of the knife edges immediately increased the sensitiveness considerably so that a difference of about 0·02 of a lb. ft. can be detected with a range up to nearly 80 lb. ft. It is hardly necessary, however, to argue this point, as no one would think of putting the beam of a testing machine, or of a chemical balance, on ball bearings, and no injury of any kind has been found to the knife edges of this brake after seven years' hard use.

The arrangement of my first brake was, however, needlessly complicated by these changes from ball bearings to knife edges, &c., and two years ago I had another constructed in which the generator was mounted on knife edges as before, and the whole arrangement mounted on a portable stand which could be readily brought up and directly coupled by means of a simple flexible coupling to any machine to be tested. This device has been found most convenient, and I propose to send you a description of it with a complete analysis of the iron, friction and other losses of a machine obtained with it. Incidentally, it may be mentioned that these tests have shown the hysteresis loss to be proportional to $B^{1.54}$ and the eddy current loss to B^2. It is possible, however, that Messrs. Davies and Shaw's value for the hysteresis exponent is not wrong as it must be remembered that we are here concerned with rotating rather than alternating fields.

Finally, as to the authors' remark that the cradle dynamometer has not met with a large measure of success, I fancy

Digitized by Google

that this has simply been because it has not been commercially available. I understand, however, that the National Physical Laboratory have been constructing a large brake on the lines of my later form, and I am quite certain that when its advantages are realised it will become the standard method for accurate work, and indeed for commercial testing in works. In this belief I have recently arranged with Mr. R. W. Paul to have the portable form put on the market in various sizes. —I am, &c.,

Reigate, July 8. CHARLES V. DRYSDALE.

FISCAL POLICY AND THE ELECTRICAL INDUSTRY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In reply to the Free Trade statement "that imports of goods can only be paid for by exports of goods": this is quite correct amongst those who live on trading only. If Smith (Britisher) and Brown (foreigner) trade only with each other and have no other means of subsistence, it is obvious that trade in value must be quite equal, or one or the other would come to grief. But let us suppose Smith is a lucky man; his grandfather some 50 years ago made money and left him an income of £200 a year invested in a railway in Brown's country, this income being quite outside the trading question. Smith hears that motor cars, pianos, &c., are made very cheaply abroad, and writes to Brown not to send the £200, but to send instead that amount in motor cars, pianos, jewelry, &c., for his family to use, as they are cheaper than he can make them at home. Under these circumstances the balance of money would remain equal. Our workers would lose profits and wages to the extent of £200 (less the value of raw material). Where do British traders and workmen stand in this case? Jones makes a fortune of £50,000, say, in China or South Africa. He wants an investment for his money, and puts it into the construction of railways in the United States (to the advantage of the American workmen), and gets his £2,000 per annum for his investment. But this money is not sent home in cash, because someone else has ordered £2,000 worth of electrical machinery in the States which have to be paid for, so the balance of exchange is equal. But the British workman does not come in at all. He sees the foreigner reap the benefit both of the capital and the interest. And this is being repeated in every country. Thousands of wealthy people who have made fortunes abroad, in the Cape, Australia, India and on the Continent returning home and investing in the same manner as Jones.

Now, the Inland Revenue Report (some five years back) tells us that our British annual income from foreign investments is 63 millions a year. The returns during the past few years must have largely increased, but are not available. And this (together with Jones's money) goes to pay for our foreign manufactured goods bought abroad. No cash is sent over, but goods. And the sum is adjusted by bankers' bills. Therefore, the cash balances show no difference. Now, this sum of 63 millions per annum is interest on foreign investments, is the interest on the sum (according to good authorities) of £2,000,000,000 we made during that marvelously prosperous period from 1850 to 1880 before referred to, statistics showing but few foreign investments before that time.

The fact that imported goods are partly paid for by taxed exports must also injure our trade. Suppose a 25 per cent. tax is levied on our manufactured goods sent abroad, we should have to send over 25 per cent. less goods than the foreigner sends us, in order to make the balance of trade equal, because we have to pay the duty, against nothing paid by the foreigner.

The only people who gain directly by the admission of untaxed manufactured goods are people living on money invested abroad and pensioners. But these peoples' families and relatives, are in as awkward a position regarding employment as others. The working man in the first instance loses his wages and consequently cannot go to the butcher, grocer and draper, and cannot pay his rent. And so every one loses all round. The grocer cannot do much business, so he cannot consult his lawyer, and the lawyer loses some of his practice and has to reduce his staff. The doctor loses because his patients, having but little money, have to go to the charitable hospital. The landlord loses his rent, and will have to reduce his expenses and economise all round. Everyone losing indirectly under free manufactured imports. The following is an interesting quotation: "Berlin, April 16th, 1910.—The Conservative and Protectionist 'Kreuzzeitung' indulges in a pæan of triumph on the decay of Britain and flourishing progress of Germany. Taxation in England in 1908 amounted to 95·80 marks per head, in Germany to 48·17. Emigrants leave Britain by the hundred thousand, German emigrants are counted by tens of thousands. The Germans have in the savings banks nearly four times as much as the Britons. The abundance of capital in England, says the journal, is another sign of decay. Money is dear in countries like Germany and America, with their rapidly and powerfully growing industries, and cheap in decadent countries like France and Great Britain, whose industry is unable to absorb accumulative capital. The journal says that the explanation of these evils is largely to be found in Free Trade and the depopulation of the countryside."—I am, &c.,

Ealing, July 11. BENNETT FITCH.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: If your readers will examine Mr. Hookham's note in this week's issue I think they will find a logical fallacy underlying his first letter rather more clearly expressed. He says: "If, by a duty, you stop goods from coming in, you will stop the goods that used to pay for them from going out; that is to say, that *the employment you give on the one hand you take away on the other.*" This involves the unwarrantable assumption that exports and imports of similar selling price represent the same amount of labour.

Selling price naturally divides itself into three items: (1) material cost, (2) labour, (3) profit. Even supposing, which is not strictly true, that imports and exports balance each other on paper, it is surely evident that the country that is getting the largest proportion of items (2) and (3) is getting the best of the bargain. It seems to me, therefore, that the deductions that Mr. Hookham draws from the crude "imports pay for exports" theory are not proved.

On the other hand, in considering the effect of Protection on employment, he has overlooked the primary object of scientific tariffs—*i.e.*, the exchange of our manufactures for the other nation's raw material—and refers only to their secondary effect on home prices. It seems to me that the answer to his "challenge" lies in the fact that the tariffs will be graded in proportion to the "labour value" of the goods.—I am, &c.,

Norwich, July 12. S. E. GLENDENNING.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Your issue of July 8th contains more nutshell arguments from Mr. Hookham. In his letter the reasoning is lucid in the extreme:—

1. Imports are paid for by exports.
2. Stop the imports and you stop the exports.
3. What employment you give for the home market you take away from the export trade.

So far Mr. Hookham. But why stop there? Why does he not continue thus:—

4. Conversely, increase the imports and you must increase the exports to pay for them.
5. Buy only imported goods, and so compel foreign nations to buy our goods in exchange.
6. Eventually have every country importing all its consumption and exporting all its production, and thus attaining an almost indecent pitch of prosperity.

Mr. Hookham stops at No. 3 because he can detect the utter nonsense of 4, 5 and 6. But they are the logical sequence from his own arguments.

The truth is, of course, that there are more things in Protection and Free Trade than are dreamed of in Mr. Hookham's philosophy. It is by no means so simple a question as he appears to think, and it cannot be disposed of off hand by any "nutshell" argument. All sensible people realise that

Digitized by Google

LIBRARY OF THE UNIVERSITY OF CALIFORNIA

roughly, the total selling prices of exports are equal to the total buying prices of imports. What is not so clearly realised is that the value of the *labour* in equal values of different commodities is by no means a fixed quantity. By exporting highly manufactured goods and importing (say) raw cotton in exchange, we ensure a great gain of employment to the country. On the other hand, an export of coal balanced by an import of watches means a serious loss of employment. A tariff is an instrument whereby encouragement is given to the right sort of exchange, while the wrong sort is penalised, and the fines thus imposed are added to the country's public funds.

The total *value* of imports (and, therefore, exports) is no true index to a country's prosperity, any more than turnover is a criterion of sound business. In each case it is essential that the transactions shall be profitable. The shipping industry seems to be the only one directly affected by such a question, and even here gross tonnage is of more importance than gross value, with which it is only indirectly related. An intelligent tariff does not seek to curtail imports or to restrict trade. It seeks to encourage the profitable transaction at the expense of the unprofitable. It aims at ensuring an equality of conditions with those of other nations, so that labour, where economically advantageous, may be purchased in the country rather than abroad.

An intelligent tariff will, therefore, increase employment because (1) it will foster manufacturing for home consumption, (2) it will encourage payment for imports by *manufactured* articles. Mineral wealth, agriculture and human activity are the sole exportable resources of any country. We *must* have imports. Let us pay for them with the work of the men now starving under a policy of foreign preference.

Mr. Hookham's first letter contained a challenge to anyone to show him how his arguments were unsound. I did so. His second letter issued a new and wider challenge. I have met it. It is now for Mr. Hookham to reply. No doubt he will again entirely shift his ground, and then claim a victory.—I am, &c.,

London, July 11. MUDRÉTZ.

PARLIAMENTARY INTELLIGENCE.

NORTH-EAST LONDON RAILWAY BILL.

On Thursday last week this Bill, which had already passed through all the stages in the House of Commons, came before a select Committee of the House of Lords, presided over by the Earl of Donoughmore.

After hearing Mr. Freeman, K.C. (who opposed the Bill on behalf of the G.E.R. Co.), the chairman intimated that the committee considered the preamble not proved, that the petitioners against the Bill had been unreasonably and vexatiously subjected to expense, and that, therefore they were entitled to recover their expenses from the promoters.

Mr. FREEMAN asked the committee not to allow the withdrawal of the Bill, but to order the promoters to proceed, and, if they failed to do so, to reject the bill. In 1905 the North-East London Railway Co. were granted powers to construct a line, partly in tubes and partly above ground, from the City to Waltham Abbey. Parliament made it a condition of the passing of that Act that within a specified period the promoters were to satisfy the Board of Trade that they had raised a certain amount of the construction capital. The promoters had failed to comply, even though they were given four extensions of time. Meanwhile the line had been blocked and the district hung up, the Great Eastern Co. being unable to carry out various works they would otherwise have carried out. A further extension of time was asked for by the promoters this year.

MINES ACCIDENTS (RESCUE AND AID) BILL.

This Bill was read a second time in the House of Commons last week.

Mr. MASTERMAN, who replied to criticisms of the Bill, said it was not suggested that they should fix on some particular type of apparatus and insist that it should be provided in all mines. Nor was it proposed that they should interfere with the responsibility of the management. If any Treasury grants were to be made they should go to the advancement of scientific knowledge through experiments. The Commissioners would not interfere with the mine management, but would see that some form of rescue apparatus was provided at the mine or in the immediate neighbourhood. They would have to see also that there were men trained to use the apparatus. The proposed Orders would be laid on the table, and if neither House of Parliament objected they would become law. The masters would provide the apparatus, and the men would have to provide men trained in its use. At every mine where an explosion had occurred in the last ten years messengers had been hastily despatched for rescue apparatus which very often had been of no use because of the distance it had had to be brought and because nobody knew how to use it. At Whitehaven the apparatus did not arrive until 17 hours after the disaster. There were two sets, one from Newcastle and the other from Lancashire. The first was without the necessary liquid air, and the second without the electric light. If this apparatus could have been used within half an hour of the disaster, by men trained in its use and knowing the pit, it was likely that there would have been a smaller loss of life.

WIRELESSS TELEGRAPHY ON SHIPS.

In the House of Commons on Wednesday Sir E. SASSOON obtained leave to introduce a bill to render the installation of wireless telegraphy on passenger ships compulsory. He said experience had shown the value of that marvellous invention for the preservation of human life and property, and he did not anticipate that shipowners would grudge the cost. It would be an obligation such as Parliament had imposed upon railway companies in the use of brakes. From such inquiry as he had made the expense of installation would not be more than £200. The main item of expense would be that of an expert operator, and in these days of diffusion of technical knowledge for small vessels that expense might be avoided or reduced by simplification of apparatus and by utilising the services of the engineer or junior engineer. The increased demand that would follow the passing of the bill would tend to reduce the cost of the apparatus, and there would be compensation in reductions in premiums for insurance. The cost of assistance to the steamer "Trieste" would have been reduced by the use of wireless telegraphy. In New Zealand the Government authorities had power to enforce such an obligation upon vessels; that was also the case in France, and a like proposal was before the Italian Parliament. The bill, which would come into operation in 12 months from its passing, would make it unlawful under a penalty of £1,000 for a vessel carrying passengers and crew to the number of 50 to leave port without having installed an apparatus for transmitting and receiving messages over a distance of 100 miles. The company installing would be under obligation to receive and transmit messages, and the Board of Trade would be required to frame regulations. Coastwise vessels would be exempted.

Mr. T. GIBSON BOWLES, who opposed the introduction of the bill, thought there was great danger that in its operation the measure would do more harm than good. Large steamers had to a great extent wireless telegraphy installed. To small steamers the expense would be a matter of great importance; not every tramp steamer could bear the expense of £200. There would be in addition the expense of carrying two men to work the apparatus, for one man could not be on continuous duty, and the engineer had his work in the engine room to attend to. Nothing had hampered English shipping more in the past than the manner in which it had been regulated. The system had done nothing but mischief, and had ruined hundreds of shipowners. It was proposed to institute a further set of regulations to be carried out by the Department which had oppressed and strangled shipping as much as they could. It was no use installing wireless telegraphy on board ships unless they had a sufficient number of stations on land to receive the messages. Between this country and New York there were many stations, but they were under the control of the Post Office, and, like everything else under the control of a public Department, they were hundreds of years behind the times. They were so bad as to be almost useless, and there was no hope of any improvement. Regarding other parts of the world, when they got to Australia and India there was scarcely a station to be found, so that passenger ships had to go many thousands of miles without being able to use wireless telegraphy.

The bill was read a first time.

LONDON ELECTRIC SUPPLY BILL.

The Select Committee of the House of Commons on this Bill met on Tuesday, under the chairmanship of Mr. Brunner.

The Bill, which is promoted by the Board of Trade, constitutes London County Council the purchasing authority of the undertakings of the Kensington & Knightsbridge and Notting Hill Electric Lighting Cos., the St. James' & Pall Mall Electric Light Co., the Westminster Supply Corpn., and the Central Electric Supply Co. The Bill complements the Electric Supply Act of 1908.

There was no opposition, and the Committee found the preamble of the Bill proved.

RHONDDA URBAN DISTRICT COUNCIL (TRAMWAYS EXTENSION, &c.) BILL.

On Tuesday a Select Committee of the House of Lords (presided over by Lord Donoughmore) passed the preamble of this Bill, which authorises certain extensions of the system, including a line to Maerdy. The Taff Vale Rly. Co. opposed, on the ground of competition, but, after hearing the evidence, the Committee allowed the Bill to proceed.

Telephone Time Limit.—In reply to a protest by the Bradford Master Builders' Association, the National Telephone Co. state that the time limit of 3 minutes for local calls applies to junction lines only. It is not new, but it has not been enforced in the past and this has resulted in dislocation of the service. The company has the right to disconnect any call at the expiration of three minutes, but the right is not exercised except in the cases of trunk and junction calls.

LEGAL INTELLIGENCE.

Attorney-General ex rel. India Rubber, Gutta Percha & Telegraph Works Co. v. West Ham Corporation.

On Tuesday, Mr. Justice Neville commenced the hearing of this action for a declaration that large overdrafts obtained by defendants from the London and County Bank in respect of their electricity undertaking were unauthorised and illegal and that the Corporation were not entitled to levy a rate for paying off such overdrafts or interest thereon. An order was also asked for to compel the bank to refund the interest already paid to them in respect of the alleged illegal overdrafts.

Sir Alfred Cripps, K.C., M.P., Mr. MacMorran, K.C., and Mr. Joshua Schofield appeared for plaintiffs; Mr. Danckwerts, K.C., Mr. C. Morten, K.C., and Mr. Tomlin for defendants; and Mr. Buckmaster, K.C., and Mr. Methold for the Bank.

In opening the case, Sir ALFRED CRIPPS said some crucial points were raised as to what was illegal and improper on the part of a Corporation when dealing with its borrowing powers. It was alleged that defendants had expended large sums in respect of their electricity undertaking without any statutory authority. Having exhausted their authorised or statutory borrowing powers, they had, without any legal authority, obtained an overdraft from their bankers. The total commitments at one time under that head amounted to £150,000, not one penny of which was authorised either by statute or by the L.G. Board. If a Corporation was to be allowed to borrow on an overdraft after they had exhausted their statutory borrowing powers, all restrictions imposed by Parliament to ensure fair trading would be absolutely valueless. When it was found in March, 1908, that there was a deficiency of £44,000, instead of it being met as the Act contemplated, illegal borrowing was resorted to. The Corporation had purported to use their general statutory borrowing powers as security for obtaining advances for their electrical undertaking. That was, he submitted, wholly illegal and improper. Further, provisions for sinking fund had not been complied with. The sinking fund, which had amounted to £90,000, instead of being invested in outside securities, as it should have been, was set off against the overdraft obtained from the bank. Such a way of dealing with local funds could not possibly be justified. The Corporation had chosen a London Bank of high standing, but they could choose their own bank, and supposing that they had chosen a bank less stable there was no telling what might have become of all their money. The money they had raised under their statutory powers might have been lost altogether. He could not conceive any more improper use of their financial powers than in using their sinking fund in order to obtain an improper overdraft instead of investing it in a legal and authorised manner. It was intended that that fund should be invested for the benefit of future ratepayers. The Electric Lighting Act of 1882 showed how the expenses of a local authority for electric light were to be met. It provided that any expense incurred by a local authority under the Act (including expense of obtaining powers or of meeting opposition to obtaining such powers) might be defrayed out of the local rate as defined in a schedule to the Act. The local authority might cause such rates to be levied as might be necessary to defray such expenses. Sec. 8 of that Act provided that the local authority might from time to time borrow money on such security and subject to such consent as was mentioned in the schedule. Such borrowing was subject to the same restrictions as borrowing under the Public Health Act, 1875, but it was not alleged with regard to the borrowing in question in the present action that the Act of 1875 was complied with or that any sanction was obtained from the L.G. Board. It was important to notice that any deficiency of income of any one year not met out of the reserve fund should be payable out of the local rate. It was clearly the intention of the Legislature that the Corporation was to carry out its electric light undertaking on a fair and proper business basis. If there was a deficiency in any particular year the ratepayers were to bear it. The ratepayers of that year would then be in a position to see how the electricity undertaking was being carried out for them by the Corporation. What happened was that a continuing deficiency from year to year which ultimately amounted to nearly £50,000 (at all events over £44,000) was never met or answered out of the local rates. Instead of which there was illegal borrowing by overdraft at the bank. Plaintiffs believed that there was at present outstanding a deficiency on revenue account of over £44,000, and that amount had been secured by illegal borrowing. Corporations were under a statutory obligation to pay their debts year by year, and if there was any deficiency to pay the debt out of the local rates, the debt was the ratepayers', and it was required that they should pay their way as they went along, because if not they had a debt that was a burden upon future ratepayers with which they were not concerned and ought not to be called upon to bear. Persons who, for the time being, had the benefit of that electricity undertaking should also make up any deficiency (if any) and not leave it as a charge against future ratepayers. So far as current expenses and revenue was concerned, the Corporation had no power to borrow. The West Ham Corporation Act, 1893, gave the Corporation power to purchase electrical fittings incidental to their supply, but it was important to bear in mind that any expense incurred by the Corporation under the sections of that Act was to be deemed an expense incurred under the Electric Lighting Act of 1882 where not otherwise provided for. Sec. 52 of their provisional order of 1892 gave the Corporation power to borrow, but only power to borrow in accordance with that section. It could only be done as a charge on the local rates with the sanction of the L.G. Board. He did not find that those powers were ever exercised or purported to have been exercised in respect of the amounts of which plaintiffs complained. There was a slight difference between the parties as to the figures in the accounts, but he thought it would appear that the accounts up to March 31, 1908, showed that the electric lighting account had been overdrawn to the amount of £44,952. 12s. There were other sums amounting to £90,000 odd, and at that time the Corporation had got an overdraft without authority of £148,671 odd. According to the bank they had lent nearly £150,000, which was wholly illegal.

His LORDSHIP asked how were the electric undertaking accounts kept. Were they balanced each year?

Sir A. CRIPPS said they were made up each year to March 31.

His LORDSHIP said then he could know whether there was a profit or loss. The accounts so far had not shown that. All they had shown was that the Corporation had overdrawn the electric lighting account. It was important, as it might be that there was sufficient to pay off the overdraft each year.

Sir A. CRIPPS said he did not think that his lordship would find that was so. What he would find was that after the matter had been considered by the Finance committee a communication was made to the bank with reference to this overdraft, the amount of which was very large indeed.

Mr. Justice NEVILLE said that from remarks that had fallen from Mr. Danckwerts he gathered that the parties were not really agreed as to the facts. Under these circumstances was it possible to proceed with the case until the accounts of the Council had been taken?

Sir ALFRED CRIPPS thought so. There would be sufficient to explain what the course of dealing with the funds had been, which would enable his lordship to determine the principal question.

Mr. DANCKWERTS suggested that it might be more convenient to take the accounts first, but his Lordship said that if Sir Alfred thought there was a question to be determined first he must hear the case.

Sir ALFRED contended that it made no difference whether the loan was for a limited time or continuous, for if the overdraft was renewed from time to time the Corporation were working upon what plaintiffs said was an illegal overdraft. Dealing with the correspondence, counsel submitted that it showed the overdraft was being used for revenue purposes. He submitted that the Corporation could not borrow in the way the correspondence showed they had borrowed. They could not borrow generally under their powers to borrow. They must borrow for a specific purpose, and having obtained power to borrow for that specific purpose they could not use the money for another purpose. Further, he submitted that, without putting themselves in a position to raise money by permanent loan; they could not raise it by overdraft. According to the minutes of the bank the overdraft was for the general purposes of the Corporation. They showed that the whole position was brought to the notice of the bank and the bank was cognisant of all that was going on.

His LORDSHIP put the case of where the Corporation had been authorised to borrow but were advised by their broker that the state of the money market made it inexpedient to borrow at that time, and consequently went to the bank and asked for a temporary overdraft. That, he suggested, would be legitimate.

Sir ALFRED thought not, unless as a temporary expedient. His case was that what the Corporation had done was not done by way of temporary expedient, but by way of a continuous overdraft. You could not, as against illegal borrowing, take advantage of the Consolidated Loans Fund. A great part of the overdraft was for expenditure that had not been sanctioned. Whether or not the Corporation could be entitled to borrow in anticipation of obtaining powers to do so, there could be no authority for setting the balance of the loans fund against unauthorised borrowings. Here, in the words of the reported case, the Corporation had not merely a temporary borrowing but a normal floating debt, and the whole of the authorities were to the effect that such a debt was illegal. Speaking broadly, on the authorities, his contention was that the Corporation had no power to arrange for an overdraft, apart from the consolidated fund, except for purely temporary purposes, and that the pooling of the accounts was absolutely illegal and could not be justified. The present case practically related entirely to the electric lighting account, and it would not in evidence be necessary to go into the other accounts in anything like detail, but it would be necessary to refer to them for showing how the accounts of the Corporation were kept and the general impropriety.

Mr. LEON KEEN, C.A., said that he had investigated the accounts of the Corporation for three years—from April 1, 1905, to March 31, 1908. For the quarter ending March 31, 1908, it appeared that on the electrical fund revenue account there was an overdraft of £44,952. 12s. and that the capital on the electrical account was overdrawn to the amount of £92,452. 4s. 4d. Those figures appeared in the published accounts of the Corporation. Some £1,500 odd was deducted from the £92,452, but, in his opinion, it ought not to have been, as it was money for a special purpose and should have been carried to a special account. The revenue account included all the expenses relating to the generation and supply of electricity. It represented the expenses over the revenue obtained from the supply of current. Of that, £4,669 was for expenses incurred in 1906 and was charged to net revenue account in 1908. Stores in hand, £22,000 odd, was only another way of saying that the Corporation had borrowed from the bank to pay for those stores. The same thing applied to the motors. They were paid for out of the overdraft. The electrical accounts always showed an overdraft on revenue. The lowest was £28,000, and from 1907 it had always been over £40,000. The £92,000 overdraft of electric lighting capital account was an amount

Digitized by Google

that had been accumulating. It started at £12,000 and went up gradually, until in 1908 it reached £92,000. In cross-examination, witness said that he was given access to all books and accounts he desired to examine. There was nothing in the books to show that they were otherwise than well kept. The Corporation s accounts were audited by an eminent firm of independent chartered accountants throughout the period in question.

In reply to Mr. BUCKMASTER, K.C. (for the Bank), Witness said that in his examination of the books and papers of the Bank he saw nothing that would enable him to say that the Bank ever knew the source from which the moneys paid into the Corporation s general account came from or the purpose for which the money was drawn out of it.

The case was proceeding when we went to press.

Steam Regenerative Accumulator Patent.

The Solicitor-General (Sir Rufus Isaacs) recently gave judgment in the appeal from the decision of the Chief Examiner of Patents, ordering that the patent applied for by D. B. Morison in regard to improvements in the apparatus for the utilisation of intermittent supplies of exhaust steam (No. 22,025 of 1907) be sealed. In the course of his judgment the Solicitor-General said the opponents (the Société d'Exploitation des Appareils Rateau) sought the insertion of a specific reference to specification No. 3,608 of 1901, or for an amendment (by way of disclaimer) of applicant's specification, on the ground that the 1901 patent was a master patent for steam regenerative accumulators for receiving exhaust steam at irregular intervals from engines running intermittently and delivering this steam with regularity either to an ordinary condenser or to an auxiliary engine interposed between the main engine and a condenser. Applicant's first claim was for "the combination of a water heating thermal storage apparatus with a high and with a low pressure engine, and with an automatic regulating valve so arranged that, when the exhaust steam from the high pressure engine was in excess of that normally desired for the working of the low pressure engine, a part or the whole of the steam is caused by the valve to pass into the said apparatus, and be therein utilised, as far as the temperatures may practically permit, to heat water, which is thereafter, in whole or in part, withdrawn from the apparatus at an exit temperature higher than its admission temperature, and when there is no such excess the valve remains full open, and an uninterrupted passage is established from the high pressure engine direct through the valve to the low pressure engine."

Applicant's claim was for a combination including the use of an automatic regulating valve which did not form part of the invention of the opponents, and upon the true construction of applicant's claim it appeared to him that it was limited to the combination including the automatic valve, and that from the title and the description in the body of the specification his claim related to the improvements in the apparatus for use in connection with the utilisation of intermittent supplies of exhaust steam, and did not cover the use of steam regenerative accumulators for such purposes. The point of the invention was the use of the automatic valve in combination, thus providing a regularisation of the steam supply to the turbine, and his claim was therefore for a specific limited improvement only. For the applicant it was contended that the first claim of the opponents' specification should be construed by reference to the whole of the claim, the description, and the total specification, and that so considered it amounted to a claim for a specific apparatus, and must be limited to the specific apparatus described by him in his claim, and he was of opinion that this contention was correct. It was clear to him that the opponent's claim must be limited to the invention and the improvements described in the specification and claimed in the first claim, and having come to the conclusion that the opponents' claim must be limited to the specific improvement described, it was apparent that the opponents had not a master patent, and therefore a specific reference should not be inserted in applicant's specification. Sir Rufus Isaacs also held that, although it was not necessary to deal with it in detail the specifications of Jurisch (No. 1,488 of 1880), and of Duff (No. 16,985 of 1896) were sufficient to displace the contention of the opponents that the placing of steam regenerative accumulators for the purpose, and in the manner indicated in the opponents' specification was novel. He was, therefore, of opinion that the Chief Examiner's decision was correct, and that the appeal must be dismissed with 10 guineas costs.

Settle v. Sheerness & District Electric Power & Traction Co. and Queenborough Wharf Co.

The Court of Appeal (Lord Justice Vaughan Williams and Lord Justice Buckley) on Saturday heard an interlocutory appeal by plaintiff against an order of Mr. Justice Bucknill, restraining Queenborough Wharf Co. from producing to plaintiff certain letters written by the secretary of the Sheerness Co. to their co-defendants.

Plaintiff had the use of a house at the wharf of the Queenborough Co., and the Sheerness Co. supplied electricity (through uninsulated wires which passed over plaintiff's house) to the Wharf Co.'s cranes. The house had a flat roof, and one of plaintiff's workmen, who went on to the roof, touched the live wire and was killed. The dead man's relatives, who took proceedings against plaintiff, had to be compensated, and plaintiff was bringing an action for an indemnity. After the issue of the writ the secretary of the Sheerness Co. wrote the letters in question, and the Queenborough Co. disclosed them in an affidavit of documents without claiming privilege.

After argument, the Court dissolved the injunction, but declined to make any order for the production of the letters, holding that they had no bearing on the issue.

Marine Electric Propulsion Patents.

On 7th inst. the Comptroller-General of Patents (Mr. R. Temple Franks) had before him a question as to whether the specification of an invention by the Hon. C. A. Parsons as to the use of electric apparatus in the propulsion of ocean-going vessels infringed a patent of Mr. W. P. Durtnall, embodying his inventions of 1905. The Durtnall patent, it was claimed, was a method of so combining a high-speed engine, an electric installation of dynamo and motor and a propeller that the engine, or prime mover, could be run at its most economical speed, while driving the propeller much slower, and so raising the efficiency of the latter in relation to the power used and the speed of the vessel, without any undue loss of power in transmission. That combination involved the use of a polyphase motor, and in the Parsons specification of 1909, embodying an arrangement with a similar object, a polyphase motor is also included. Mr. Durtnall contended that his invention was the first attempt to utilise the polyphase principle in that specific manner, but ultimately Mr. Durtnall agreed that he would be quite satisfied if the specification of the Parsons patent included a reference to his own so far as the polyphase principle was concerned.

The Comptroller reserved his decision.

Compensation for Colliery Accident.

In the Hamilton Sheriff Court, Sheriff Thomson has delivered judgment in an action brought against Archibald Russell (Ltd.) by the representatives of the late John Wallace, miner, who was killed in defendants' colliery.

In giving judgment, the Sheriff said on Dec. 8, 1909, deceased was requested by his brother (an oversman in the pit where the accident occurred) to give assistance to men at work in a chamber which was being prepared for an electric motor. Deceased assisted in the removal of some hutches, and after they had been removed he was seen, perhaps a minute before the accident occurred, leaning against a prop in the chamber. On the opposite side of the prop a coil of electric cable was hanging: the cable was not at the time fully connected up, but the voltage of the circuit was high enough to be fatal to a person who should receive a shock from it. Three lamps had been connected with the cables but two had been removed and the remaining one was employed in lighting the chamber. The holders of the two lamps which had been removed were left on the cable, and anyone would receive a shock who put his fingers on those. A notice was posted up in the mine warning unauthorised persons not to touch cables or other electrical apparatus. Deceased had no authority to touch these things. A minute later deceased was heard to give a cry of pain, and he immediately collapsed and fell against the iron plate which was only a few inches away. He had a coil of the cable in his hand at the time. He expired at once, and the cause of death was electric shock from the cable. When his brother heard his cry he instinctively removed the coil of cable from the prop and threw it on the ground, and current was switched off. The doctor who was sent for found life extinct, and discovered on the breast of deceased a mark as of a burn of recent origin, but he could not say whether the burn was due to electric shock. The cable was in perfect condition when put in a few days before. After the accident it was found damaged to some extent, and denuded in some places of its insulation. The oversman had power, in cases of emergency, to put ordinary miners to other work, and the oversman (David Wallace) considered it a case of emergency which justified his putting deceased to work in the chamber. He (the Sheriff) found that under the circumstances the death of deceased was due to an accident arising out of and in the course of his employment, and that pursuers were entitled to compensation, which he assessed at £300.

North-Western Electricity & Power Gas Co.—In the Manchester County Court on Monday Judge Parry had before him a petition by the trustees and executors of the will of J. H. Gartside for the compulsory winding-up of this company. It was, however, announced that since the matter was previously before the Court the parties had come to terms, under which the petition would be withdrawn, the Company undertaking to pay the taxed costs. The petitioners thought there was a chance of the Company being resuscitated, and wished to give them every possible facility. Judge Parry confirmed the agreement.

MUNICIPAL, FOREIGN & GENERAL NOTES.

APPOINTMENTS VACANT AND FILLED.

An important Italian firm manufacturing electric motors and transformers require a competent works manager to supervise about 1,000 men. Applicants must be certified engineers of Italian nationality, and have already filled a similar position in a manufacturing firm. See an advertisement.

A large manufacturing Company require a first-class foreman for their winding department. See an advertisement.

The committee of the Tottenham Polytechnic invite applications from teachers of electrical engineering to prepare students for the City and Guilds examinations. The teacher will be required to attend on two evenings a week from 7:30 to 9:30. Fee 12s. 6d. per evening. Forms of application from Mr. J. W. Tomlinson, the

Digitized by Google

Polytechnic, South Tottenham, to whom applications by 21st inst. See advertisement.

Applications are invited for the positions of assistant in the mechanical and electrical engineering department of the Municipal Technical School, Halifax (at a commencing salary of £160 per annum), and lecturer in mathematics (specialist in practical mathematics), at a commencing salary of £150 per annum. Forms of application (to be returned not later than July 28) may be obtained from the Secretary of the Education Offices, Mr. W. H. Ostler, Halifax. See also an advertisment.

Applications will be received until Sept. 10 for appointment to the Henry Overton Wills Chair of Physics at Bristol University. Salary £600 per annum. Particulars from the Registrar.

Bombay Corporation require an executive engineer with knowledge of all branches of municipal engineering, including lighting and electricity. Minimum monthly salary R.1,200 (£80), maximum R. 2,000 (£133. 6s. 8d.). Applications to Mr. G. Midgley Taylor, Caxton House, Westminster, S.W., by July 31.

A professor of pure and applied chemistry is required at the Municipal Technical Institute, Belfast. Salary £350, increasing to £400. Particulars from the Principal. Applications by noon July 20.

On Wednesday the Birmingham Electrical Supply committee had before them the applications (322) for the position of secretary to the electric supply department at a salary of £600 per annum.

A sub-committee had selected 11 candidates, and four of these were before the committee on Wednesday, when Mr. Howard Foulds, secretary of the Electrical Standardizing, Testing and Training Institution, was appointed. The other three candidates selected for interview were Messrs. W. E. Foden (assistant sec. Manchester electricity department), W. T. Green (chief clerk Leeds electrical supply department), and E. J. Jennings (sec. Marylebone (London) electric supply department).

Colchester Council have appointed Mr. W. Frisby, who has been for the past three months in charge of the electricity department, borough electrical engineer at a salary of £250, rising by £10 yearly to £300.

Mr. A. L. Gardener, late rolling stock superintendent of the Wolverhampton district tramways and of the Burton & Ashby Light Railway Co., has been appointed tramway superintendent of the Isle of Thanet Electric Tramways & Lighting Co.

Watford Council have appointed Mr. G. D. Vickers, of Birmingham, assistant electrical engineer. Mr. W. Jessop (Eastbourne) and Mr. R. B. Craig (Bermondsey) were also interviewed by the Council.

Mr. A. E. Bolter, assistant secretary of the G.W. Railway Co., has been promoted to the position of secretary, on the retirement of Mr. G. K. Mills.

EDUCATIONAL NOTICES.

City and Guilds of London Institute.—The entrance examinations of the City and Guilds Central Technical College, Exhibition-road, S.W., and the City and Guilds Technical College, Finsbury, E.C., are held in September, and the sessions commence in October.

Both institutions provide courses of instruction in engineering, chemistry, mechanics and mathematics, &c. Particulars of entrance examinations, scholarships and courses of study may be obtained from the respective colleges or at the head offices of the Institute, Gresham College, Basinghall-street, London, E.C. The Central Technical College is intended for higher technical instruction for day students not under 16 years of age, preparing to become civil, mechanical or electrical engineers, chemical or other manufacturers and teachers. The college is a school of the University of London, and forms the engineering section of the Imperial College of Science. The courses of the study for the associateship of the Institute cover a period of three years.

The City and Guilds Technical College at Finsbury (London, E.C.) is designed for day students preparing to enter engineering and chemical industries and for those who have already served an apprenticeship and also for evening students. The day courses in mechanical or electrical engineering cover two years and those in chemistry three years.

University of Glasgow.—The next session will commence on Oct. 17 and end on March 23, 1911. In the departments of engineering, mining and naval architecture students usually spend the summer months in practical work, thus receiving their training on the Sandwich system. Prospectus of the course for the degrees of B.Sc. and D.Sc. in engineering and syllabus of classes may be obtained from the Assistant Clerk, Matriculation Office, The University, Glasgow.

University of Manchester.—The new session commences on Oct. 4. New and enlarged engineering laboratories have been erected. Prospectuses, giving particulars of the lectures, laboratory and drawing courses in engineering and physics, &c., may be obtained from the Registrar.

BRITISH AND COLONIAL.

Aldershot.—The Council have applied for sanction to a loan of £2,300 for the electricity department.

Association of Engineers-in-Charge.—On Saturday last about 60 members of this association visited the works of Messrs. Davey, Paxman & Co., at Colchester, the visitors having been previously entertained to luncheon by the firm at the Liverpool-street Station Hotel.

The visitors arrived at the works about 3 p.m., and were shown round the establishment by Mr. William Paxman and members of the staff. Much interest was taken in a tandem compound steam engine of the Paxman-Lentz type, fitted with positive valve gear, developing some 450 I.H.P., which was shown under steam; also in the firm's economic boilers, a large number of which were seen in course of construction in the boiler shop. (An order for five of these boilers has been received for the new Essex County Asylum at Colchester.) Other engines seen in course of erection or running included a 30 in. by 60 in. coupled winding engine with 12 ft. drum, gas engines, benzine engines, high-speed vertical steam engines, and horizontal slide-valve engines of various types.

After the tour through the various shops, which occupied nearly three hours, tea was provided in the large fitting shop.

Australasia.—The "Australian Mining Standard" states that Hay (N.S.W.) Council have let a contract for the electric lighting of the town and for the electric pumping of water and sewage for 15 years, after which period the Council may purchase the plant at a valuation.

An Order in Council was recently passed to authorise the South Gippsland (Victoria) Creamery & Butter Co. to supply electricity for lighting the town of Yarram Yarram.

The report of the directors of the Mount Lyell Mining & Railway Co. (Tasmania) for the year ended March last states that the requirements of the township of Queenstown of electric light provided by the company have much increased, and the transmission line has been improved during the year. On the termination of the original agreement a new one has been entered into with the municipal Council.

The electric lighting of the town of Glenelg by the Adelaide Electric Supply Co. was inaugurated on May 12.

The official opening of the Malvern–Prahran tramway took place on May 30. The capital expenditure by the Tramway Trust is £72,000. St. Kilda, Prahran and Malvern Councils have applied for authority to construct a line along Dandenong-road.

Additional generating plant of 2,000 H.P. has recently been put in at the Waipori (N.Z.) hydro-electric works. The demand in hand will take 750 H.P. of the new plant.

At the opening of the State Parliament last week the Governor (Sir Thomas Gibson Carmichael) referred to the appointment of a Royal Commission to consider the future of the Melbourne cable tramways and the proposed electrification of the suburban railways.

Battersea (London).—An extension of the feeder cable is to be carried out at a cost of £1,061.

Beckenham.—At the last meeting of the Council the resident electrical engineer (Mr. J. E. Tapper) reported that the present free wiring contractors were willing to continue the existing contracts for such period as the Council might require up to the limit imposed by the balance of "free wiring" capital in hand, and it was recommended that their offer be accepted.

The Electricity committee also recommended that the Council apply for sanction to a loan of £6,000. (Mains and services, £5,000, and meters £1,000.)

In the course of the discussion, Mr. Dykes called attention to the question of free wiring, and said that the returns regarding free wiring customers connected during the past year deserved careful attention. He was not then concerned as to whether free wiring was paying as a whole or not, but members should examine the figures. There were 27 consumers, and the average cost per lamp was 23s. 4d., while the average receipt from the sale of current had gone down to 3s. 9d. Some time ago the average receipts were 7s. 9½d. per lamp, but they had gradually fallen to 3s. 9d., while at the same time the cost of connecting up those installations was increasing. One consumer with 10 lamps cost £15.7s.8d. or 30s. a light. The return they got for that was 15s. 10d. That was not business. They ought to get a definite return for each lamp wired. Another consumer with 20 lamps cost £24. 8s. 10d. and the return was £4. 17s. 6d., or 4s. 10d. per lamp. A third consumer with 20 lamps cost the Council practically the same, but the receipts were £2. 3s. 9d., or only 2s. 1d. per lamp. There was no justification for such an expenditure, and the receipts did not pay their standing charges. He urged the Council to do what Poplar had done and get a proper return for their outlay.

Bradford.—The Electricity committee recommend that, as from July 1, the following charges be made for electric current:—

Private house consumers may elect to be charged on the basis of a fixed charge of 15 per cent. per annum on ratable value, plus ½d. per unit

Digitized by Google

for energy consumed, this charge to include meter rent. In the case of arc lamps, a flat rate of 3½d. per unit to be charged for energy supplied through separate meter, these meters being regarded as sub-meters and so charged. Where arc and incandescent lamps are supplied through one meter, the existing flat rate of 4d. per unit to be charged.

In the case of power, heating and cooking, in the existing rate applicable to private consumers, the maximum demand to be reduced from not exceeding 10 to not exceeding 5 kw., and in the rate for large power stations the maximum demand to be reduced from exceeding 10 to exceeding 5 kw. The scale of discounts to be altered as follows:—Exceeding 10 and not exceeding 20 kw. 2½ per cent.; 20-30, 5 per cent.; 30-40, 7½; 40-50, 10; 50-75, 15; 75-100, 20; 100-150, 25; over 150, 30. In cases not covered by this scale the discount not to exceed the maximum discount already in force. In the case of all future connections as regards all classes of consumers, a minimum charge of £1 per half-year (inclusive of meter rent), to be enforced, whether energy to that amount is used or not, the existing provision as to minimum charge being rescinded.

The charges are based on the average price of coal consumed at the electricity works remaining at 9s. per ton, the price per unit charged consumers to be increased or reduced by 2½ per cent. for every 1s. or portion of 1s. the average price of coal is advanced or reduced, no increase or reduction if the average price of coal does not exceed 10s. per ton or fall below 8s. per ton.

On Tuesday when the recommendations were submitted to the Corporation, Mr. PALIN inquired whether the committee had taken into consideration the desirability of selling electricity at a more favourable rate in Thornbury, Laisterdyke and Tyersal, in order to compete with the outside gas companies.

The CHAIRMAN (Ald. G. H. Robinson) said the committee already supplied some part of Tong, and they would be pleased to lay mains to compete with the gas company in Thornbury if the Finance committee thought it wise. It was possible for a shopkeeper, if he consumed electricity long enough, to get it at 1½d. a unit for lighting. Shopkeepers as a rule were unprofitable consumers because they were short-hour consumers.

The recommendations were adopted.

Camborne.—The Urban Electric Supply Co., which has entered into a contract with the Dolcoath Mine (Ltd.) for the supply of electrical energy for power and lighting, has notified the Council that it will apply for a provisional order or make arrangements for taking a transfer of the Camborne Electric Lighting Order of 1899.

Cardiff.—The Council are negotiating in regard to the supply of electricity in Llandaff and Dinas Powis, but the subject has been deferred pending a report from the Parliamentary committee as to the extension of the city boundaries.

Carlisle.—A discussion took place at the Council meeting on Tuesday as to the appropriation of the profit (£3,050) on the electricity undertaking, and eventually it was agreed to allocate £1,000 to relief of rates and £1,000 to reserve, carrying forward the remainder.

Chatham.—Owing to the extended use of metal filament lamps, the Kent Electric Power Co. propose to discontinue the maximum demand system, and to adopt a new scale of charges.

Consular Service.—On the 7th inst. a meeting was held at the House of Commons to consider the present position of the British Consular Service and the possibility of its improvement. The notice convening the meeting stated that as a result of a preliminary consideration of the question by a special sub-committee of the London Chamber of Commerce, the following general propositions had been agreed to as a basis of possible recommendations:—

(1) That as far as practicable the British Consular Service should be confined to British subjects, whether paid or unpaid.

(2) That as regards certain important countries (*e.g.*, Germany, Russia, Scandinavia), where there are now a considerable number of foreigners acting as British Consuls or Vice-Consuls, such countries be divided into districts with a British subject in charge.

(3) That the status of British Consuls generally should be raised (*a*) by examinations, (*b*) by adequate remuneration for their services, (*c*) by giving greater encouragement to young men to qualify themselves for the Consular services.

Mr. McKinnon Wood, who was present, was understood to have assured the meeting that the Foreign Office would be willing to consider the appointment of paid consuls where it was thought the circumstances justified the expenditure.

Crewe.—The Council have been asked to extend the electric supply mains to the new garden city at Wistaston.

Crewkerne.—Messrs. J. & A. Purves propose to apply for a provisional order forthis district.

Dromore (Ireland).—Mr. Pegg, of Belfast, has been authorised to prepare a report on electricity supply.

Eccles.—The Council have received sanction of the L. G. Board to a loan of £3,234. 3s. 10d. for extensions of the electricity undertaking.

Electric Cables under the Clyde.—The Clyde Valley Electrical Power Co. have recently laid six new electric cables under the Clyde at Yoker.

The cables in the river bed have been damaged by passing vessels, and only a few weeks ago one was rendered unworkable from that cause. The company have dredged the river from the Yoker side to the Renfrew side at the railway pier to a depth of 30 ft. below the low water mark, and at this part the new cables have been laid. Three of them are for conveying current at extra high tension (11,000 volts) while the other three are relays. With the placing of the cables at a greater depth it is expected that they will be more immune from damage than formerly.

Electricity in Mining.—At the meeting last week of the Mond Nickel Co., Sir A. Mond, M.P., said they had erected a hydro-electric power station to supply electric power for the mines and smelting works at their Victoria Mines. The plant was running satisfactorily. In order to comply with the charter of the Ontario Government with regard to way-leaves, &c., they formed a Canadian company (the Lorne Power Co.) the shares of which were mainly held by their company.

Faversham.—The electrical engineer (Mr. G. Somerville) has reported that during the past year a saving of 9,800 units on public lighting had been effected by the conversion of 48 Nernst lamps to metal filament, and recommends that the remaining 53 Nernst lamps be converted during the current year. The recommendation has been adopted.

Grangemouth.—The Scottish Electric Power Co. are laying cables in this district, and hope to be able to supply energy by Aug. 15.

Hammersmith (London).—For some time past negotiations have been in progress with the Inland Revenue authorities with a view to obtaining an alteration in the basis of assessment of the profits of the electricity undertaking for income tax.

Up to 1904-5 it was the practice to allow from the gross profits a fixed sum of £2,500 to cover depreciation in machinery and plant. This was considered insufficient, and claim was made for a larger allowance. Ultimately it was arranged to allow each year fixed percentages on the capital outlay on mains and machinery of 3 per cent. and 5 per cent. respectively. No income tax has been paid since 1904-5, but for the three years ended March, 1908, £1,920. 5s. 4d. had been set aside to meet the liability. On the basis now arranged, the income tax payable in respect of these years will be £1,298. 14s., or £621. 11s. 4d. less than the amount provided.

India.—H.H. the Nizam has sanctioned a scheme for the supply of electricity in a part of the city of Hyderabad.

Callenders Co. are to supply and lay the mains and Messrs. Osler & Co. to do the wiring in private houses. The generating plant is to be erected at the Mint, and the use of the same engines for driving the electrical and the coin manufacturing plant is expected to result in economy. Supply of current will probably commence by the end of August.

Lahore Municipality propose to erect and equip electricity supply works at a cost of about 5,00,000 rupees, for lighting the Civil Lines at Lahore.

Japan British Exhibition Awards.—The Superior Jury of the Japan-British Exhibition has completed the examination of the awards, numbering between 5,000 and 6,000. The distribution is to be made in the Congress Hall of the White City to-day (Friday), at 3:30 p.m., when H.R.H. Prince Arthur of Connaught will preside. The prizes will be distributed by the Duke of Norfolk to the Japanese Exhibitors, and by Baron Oura to the British Exhibitors. It is notable that the awards are ready for distribution during the actual progress of the Exhibition.

Leicester.—The Gas and Electric Light committee have abandoned their intention to appeal against the recent decision of Mr. Justice Neville declaring wiring work and the supply of electrical fittings, &c., by the Corporation to be ultra vires.

Light Railways.—The Llanelly and District Light Railways (revival and extension of time) Order has been submitted to the Board of Trade for confirmation. Objections by July 27.

Liverpool.—A sub-committee of the Tramways committee has reported against the proposal to run express electric tramcars.

Macclesfield.—The Council have received two notices of intention to apply for provisional electric lighting orders.

Malvern.—The Council, on the recommendation of the engineer (Mr. W. J. Rendell Baker), has decided to cancel the present maximum demand system (2½ units for each 8 c.p. lamp wired), which has resulted, since the higher candle-power metallic came into vogue, in a greater percentage of the consumption being charged upon the higher rate. The engineer's recommendation was for a flat rate of 6d. per unit, less 5 per cent. for cash in 28 days, with increased discounts for larger consumers. The Council, however, decided to give the system a trial at a universal rate of 6d. per unit, less 5 per cent., representing practically 5 per cent. reduction to all consumers.

Marylebone (London).—The Electric Supply committee recommend the Council to enter into agreements with Mr. A. Hugh Seabrook, general manager, Mr. C. Jennings, secretary and accountant, Mr. Richardson, station superintendent, Mr. Smyth, mains superinten-

Digitized by Google

dent, and Mr. Holmes, sales manager of the electricity supply department, on the following terms:—

(1) That there shall be an advancing salary for four years. (2) That each officer shall be bound to serve the Council during this period, but that he may be dismissed on payment of six months' salary, or without compensation in the case of misconduct or of illness lasting beyond six months. (3) That 6 per cent. out of the profits on the first £10,000 net profits in any year and 9 per cent. on anything beyond £10,000 shall be allotted proportionately among the officers affected as extra remuneration. This will only be paid in the event of a growth in the sales at the rate of 500,000 units a year, and a diminution in the average price of 5 per cent. each year. The Council will keep absolute control as to reducing prices.

It is proposed that Mr. Seabrook be granted an annual increase of salary of £50, plus 2 per cent. on profits up to £10,000, and 3 per cent. on profits beyond. The other officers are recommended for annual advances of £25, plus 1 per cent. on profits up to £10,000 and 1½ per cent. on profits beyond.

Municipal Telephony.—The accounts of the Portsmouth municipal telephone department for the year ended March 31 show total income of £11,721 (against 11,285 in 1908-9), including £9,123 for exchange rentals, £194 for private rentals, £470 for local tolls, £351 for public telephones, £80 P.O. royalty and £94 terminal fees from the National Telephone Co., also £1,340 trunk and terminal fees and £60 for interest.

The working expenditure was £7,028, and included £948 for line repairs, £124 for line reconnections, £1,246 for instrument and exchange repairs, £793 salaries and office wages, £1,396 operators' wages, £1,030 royalties and P.O. commission, £278 terminal fees to National Telephone Co., £611 rent, rates and taxes, and £165 for wayleaves. The gross profit was £3,293, and after taking credit for amount brought forward and paying interest (£1,463), instalment of principal (£1,465) and income tax (£36), the balance (£530) was transferred to reserve. The capital expended is £53,154, an increase of £772. There are 2,556 telephones working, exclusive of junction lines. There are 1,953 subscribers' lines (decrease 39), 627 extension and other lines (increase 50) and 10 exchanges (as in 1908-9).

Oldham.—It is probable that the Council will apply for a provisional order for Royton, as there seems to be a fair demand for electricity supply in that district. At present the Lancashire Electric Power Co. have authority to supply for power, but not for lighting.

Osrams in Glasgow.—Unquestionably one of the finest examples of street illumination by metal filament lamps, is to be found in Glasgow, where, by their highly successful trials, "Osram" lamps are in favour for the lighting of important positions. A walk down Queen-street—a wide and busy thoroughfare—will convince even the most sceptical that the metal filament lamp has more than secured its position in the field of "public illuminants." Its economies have all along been appreciated, and now the fragility of its filament is no longer a nightmare, it supplies the most fitting of all weapons with which to fight the gas bogies—Let there be war to the death!

The remarkable results in Queen-street are obtained by means of 30 Osram lamps—16 100-watt and 14 55-watt, all for 260 volts. These are arranged on 23 posts and have been installed since April 1, burning just over 400 hours up to date. None of the lamps have failed, and the candle-power has in no way diminished. This installation furnishes yet another proof of the strength of the Osram filament now supplied. Queen-street is a main thoroughfare, and heavy traffic passes up and down unceasingly morning, noon and night.

Pacific Cable Board.—Mr. A. S. Baxendale, general manager of the Pacific Cable Board, is in Canada formally taking over the land telegraph line across the Dominion which has been leased from the Canadian Pacific Railway Co. The staff of operators at the different stations on the line are to be appointed and controlled by the Board.

Penmaenmawr.—The L.G. Board have sanctioned, without local inquiry, a loan of £550 for the electric lighting of the promenade.

Personal.—Mr. J. W. Saaler, of Bruce Peebles & Co. was married on the 12th inst. at St. Margaret's Church, Westminster, to Miss Frances R. Knott, of Southsea. Mr. and Mrs. Saaler sail on Saturday by the R.M.S. "Saxon" for South Africa, where Mr. Saaler is taking up a position for his firm in Johannesburg, and we are sure has the good wishes of many friends.

The members of the South-Eastern district of the Institution of Municipal Engineers have elected Mr. Henry C. Adams, consulting municipal engineer, as their chairman for the second year in succession.

Provisional Electric Lighting Orders.—The Board of Trade have issued their report respecting the applications to and proceedings of the Board under the Electric Lighting Acts, 1882 to 1902, during the past year.

Of the 25 applications 14 were made by local authorities and 11 by companies or persons; 20 orders were granted. In three cases (Ballyclare, Brumby and Frodingham, and Templemore) the Board were not satisfied that an undertaking could be established without involving the Councils of the districts in a loss. The Frimley Council did not proceed with their application, and owing to a technicality Messrs. R. A. Lister & Co. were unable to proceed with their application for Brixham and Totnes. In the case of Runcorn the Parish of Weston was allotted to the Castner-Kellner Alkali Co. and the urban district and the remainder of the rural district were given to Messrs. G. H. Cox and H. J. Falk. The local authorities of Ardrossan and Smethwick refused to give their consent to the applications for orders for those districts, but after holding local inquiries the Board dispensed with their consent and granted orders.

Provisional Order Revocation.—The Board of Trade have revoked the Heswall Electric Lighting Order, 1908, as from July 2.

Salisbury.—The local Electric Light Co. intimate that they propose to apply for a provisional order to extend their area of supply so as to include the whole of the borough.

Sevenoaks.—The Council have referred to a committee a report from Messrs. Mordey & Dawbarn on the question of electricity supply.

The report states that, judging from somewhat similar residential districts, in the third year of working the consumption by private consumers would reach about 60,000 units. At 6d. per unit, the cost to the consumer would not be more than that of gas at 3s. 2d. per 1,000 for the same standard of illumination. If an electric supply scheme should be adopted, street lighting should be included, because the revenue derived from it would cover the entire working cost of the first year, leaving capital charges only to be met by revenue from private consumers, thus avoiding the risk of any serious charge on the rates during the initial stages of the undertaking. In their estimate Messrs. Mordey & Dawbarn have allowed for distributing cables aggregating about 4¼ miles. The estimated initial outlay is as follows:—Power station site, building and plant (including two petroleum engines and dynamos, each of 60 kw. capacity, one being spare, and a battery of accumulators), £5,427; distributing cables for private lighting, with 200 service connections, £4,918; distributing cables for street lighting (including assumed purchase of pillars and lanterns from the Gas Co.) £5,623; total £15,968. If the Board of Trade allowed overhead wires in the outlying portions of the district the capital outlay would be reduced. On the first year's working there would be a deficit of £345, assuming the sale of 20,000 units for private lighting and an income of £1,058 from street lighting (303 lamps), and in the second year there would be a profit of £181.

Sheffield.—The Tramways committee have decided to make a further trial with the latest method of Thermit rail joints. The cost of the joints is put at 29s. each.

Application is to be made for power to borrow £2,500 for purchasing motors to be let on hire. Extensions of mains are to be carried out at an estimated cost of £1,144.

South African Trade.—The British Trade Commissioner for South Africa (Mr. R. Sothern Holland) writes, regarding the information bureau which has been established at Cape Town, that considerable interest is being taken by manufacturers in the development of the bureau, and he asks that copies of catalogues, &c., may be furnished him for the purpose of filing.

Stafford.—The salary of the electrical engineer, Mr. R. E. Meade, has been increased by £25 a year.

Taunton.—The Council are about to advertise for a successor to Mr. E. B. Thornhill (borough electrical engineer), at a salary of £200 a year.

Tonbridge.—The Council have applied for sanction to a loan of £1,441 for extensions of the electricity undertaking.

Torquay.—The Council has granted a honorarium of 100 guineas to the Borough Surveyor for his services in connection with the erection of a new power station. A sum, equal to three months' salary, is to be given to the widow of the late electrical engineer (Mr. P. Storey), while Mr. Keenan is to be granted £25 for extra services rendered by him during the illness of Mr. Storey.

Victorian Institute of Electrical Engineers.—At the annual meeting of the Electrical Association of Victoria it was unanimously resolved that the title of the association be changed to the Victorian Institute of Electrical Engineers.

The Papers to be read during 1910 include the following: "New Safety Regulations Concerning the Production and Utilisation of Electricity," by J. D. Gillan; "Ball Bearings," by J. D. Wearn; "Consulting Engineers at Home and Abroad," by W. F. Marshall; "Radio-active Material," by T. C. Baddeley; "Arc Lighting," by H. G. Such; "The Electrification of Melbourne Cable Tramways," by G. S. Morrison; "Electro-Thermometry," by E. B. Brown; "Electricity Recording Meters," by W. H. Alabaster and N. A. Wheaton; "Lubricants," by F. A. McCarty.

In his presidential address Mr. A. H. Jackson referred to the progress made in connection with electric traction in the cities of the various States. The Melbourne tramways would probably be electrified with the suburban railway lines. The address also dealt with the progress in the manufacture of metal filament lamps, the utilisation of refuse, brown coal and water-power in Victoria in the generation of electricity.

Digitized by Google

Wallasey.—A new tramway route, between Wheatland-lane and Wallasey Village (about 3½ miles of double track) was opened for traffic on Friday last.

Walsall.—On Monday the Corporation unanimously adopted a recommendation of the Electricity committee to put down additional generating plant at the electricity station, and to extend the mains to Birchills, Bescot and Bloxwich, at a toal cost of £23,225.

The committee also reported that they had considered an offer of a power company to supply the Corporation with electricity in bulk, but they were of opinion that such a course offered no advantage.

Mr. SLATER stated that the company's offer had commended itself to certain members of the Council who were not enamoured of municipal trading, as the company were prepared to supply the Council with current at ¾d. per unit. When the offer was scrutinised, however, it was found that a considerable loss of current occurred in the process of conversion, and the actual payment would be at the rate of about 0·94d. per unit. In addition, considerable capital outlay would have to be incurred to enable the current to be distributed, and when all the charges were met the committee calculated that the actual cost would be 1·77d. per unit. An important consideration was that if the Corporation took a supply in bulk from the company, practically the whole of their generating plant would become useless, which would entail a loss of about £37,500. That would have to be met by a call upon the ratepayers, and it was very probable the L.G. Board would insist on them making good the deficiency by three annual payments, which would mean an addition to the rates of no less than 1s. in the £. Dealing with the merits of their scheme he said that the Council were originally asked to sanction an outlay of £35,000, but as a result of a searching enquiry by a L.G.B. inspector the scheme was withdrawn for further consideration. The result had been that a proposal to build a new generating station had been abandoned and a saving of about £8,000 effected. With the new plant the committee would be in a position to supply current to manufacturers on more reasonable terms and on a system more suitable for manufacturing purposes. It was also proposed to lay mains into districts where there was a likelihood that manufacturers would find electric supply advantageous.

Wednesbury.—The L.G. Board have sanctioned a loan of £2,095 for extensions of the electricity undertaking.

West Ham.—The Thames Ironworks Co. have provisionally agreed to take the whole of their supply for power and lighting from the Corporation for a further period of three or five years.

The total income of the tramways undertaking for the year ended March 31 was £125,694, from which £3,111 is to be deducted in respect of receipts due to other authorities in connection with through running. Total expenditure was £87,561, less £1,188 for through running. The net profit (£5,737) is to be carried to reserve and renewals fund, which now amounts to £39,293.

Whitchurch.—The surveyor has been requested to collect information regarding electricity supply for the Lighting committee.

Whitehaven.—An inquiry was held here last week into the Council's application for sanction to borrow £5,293 for extensions of the electricity undertaking.

The TOWN CLERK said the loan was required for additional plant to meet the demand for electric light and for mains extensions. The Council was advised that the additional plant would enable them to reduce the cost of production. For plant £2,993 was required and £2,300 for main extensions.

The INSPECTOR (Mr. H. R. Hooper) observed that the works costs were considerably more than double what they ought to be. Their financial position was not half so bad as it appeared, and there was no reason why in a few years time they should not be in a fairly good position. He urged the necessity of improved and more reliable plant, and emphasised the necessity of pushing the undertaking.

Wimbledon.—The Council has received sanction to borrow £3,400 for mains, £1,600 for house services and £1,600 for meters.

Wireless Telegraph Note.—The Board of Trade has been approached by the Associated Chambers of Commerce urging the compulsory installation of wireless telegraphy on all passenger ships for oversea traffic. The Board has replied that, while they appreciate the importance of this question, in view of the large number of passenger vessels which have been and are being voluntarily fitted with wireless telegraph apparatus, they consider that compulsory legislation at the present moment would be premature.

Wolverhampton.—The Corporation have decided to put down water-softening apparatus at the electricity works, to renew the economisers, &c., at a cost of £1,450.

Worcester.—Mr. Parker has given notice that he will move at the next meeting of the Council that, in order to increase the use of electricity the Electricity Department be allowed to act as agents for manufacturers in the sale of heating and cooking apparatus and motors on commission (but not to undertake the sale of fittings or lamps, or the wiring of houses), on the distinct understanding that the Council are not to be liable for the price of the goods sold.

York.—An unopposed inquiry was held last week into an application for sanction to borrow £2,475 for the electricity undertaking.

The city electrical engineer (Mr. J. W. Hame) said that £1,100 was wanted for services, £800 for motors and £575 for meters.

The inspector (Mr. H. Ross Hooper) said it would be well to avoid borrowing for meters if they could. The loan for meters would only be allowed for five years. The undertaking was rather handicapped, and it would be to the advantage of everyone to stop borrowing those small sums.

Siemens Institute Annual Sports.—The annual sports of the Siemens Institute, Stafford, have come to be looked upon as one of the most important athletic gatherings in the Midlands. The grounds, the property of the firm, provide both a grass and cinder track. The fifth anniversary takes place on Saturday, Aug. 20, under M.C.A.A. laws and regulations. In addition to a full list of members' events, there are included in the programme the following open items: 10 miles walking handicap, 1 mile flat handicap, 1 mile cycle handicap, 3 miles cycle handicap, obstacle race and Boy Scouts' relay race (full dress). All athletes, especially those from other firms, will be very welcome, and can obtain further information from the general secretary (Mr. F. E. Read), Siemens Institute, Stafford.

Annual Outing.—The employés of Robertson Electric Lamps, Ltd.' had their annual outing on Saturday last at Margate. The party, consisting of the male and female employés at the Brook Green Works and their friends, numbered over 700, and were conveyed from Addison-road (from whence, by the way, you can get to anywhere) by special train direct to the famous Isle of Thanet holiday and health resort. The weather was heavy and dull during the morning, but fortunately brightened up in the afternoon. No fixed programme was arranged for the morning, the party spending their time in their own way. Lunch was served in one of the hotels on the Marine Parade, after which drives into the country in brakes engaged for the party formed not the least appreciated part of the day's enjoyment. The whole of the arrangements for the large party were well carried through, more particularly the facilities, for those who could not join the "special," to travel by ordinary train, and the management committee are to be congratulated on the complete success of their efforts. And Margate offers many attractions for a large party.

Electra House Flower Show.—The second annual show of the Electra House Rose and Sweet Pea Society (which is affiliated with the National Sweet Pea Society) was held in the large meeting hall of Electra House, Finsbury-pavement, London, on Tuesday, and, notwithstanding the vagaries of the weather this season, the exhibitors (who are all members of the staffs of the Associated Telegraph Companies) made a very attractive display.

126 exhibits were staged, compared with 43 last year. Roses were the chief sufferers from the weather, but, this notwithstanding, there were some fine examples amongst the exhibits. The chief honours in the rose classes were carried off by Messrs. Hale, Hardie, De Merrall, Hibberdine, E. A. Roberts and Lindford. In the sweet pea section there were some really charming blooms, and keen competition resulted. Capt. Pattison secured the two best prizes, but it was agreed that the chief honours rested with Dr. Curtis, whose exhibits were the subject of warm appreciation from the judge (Mr. W. A. Billey, J.P., F.R.H.S.). Messrs. Hardie and Hibberdine each obtained a first prize in the sweet pea section. Amongst hardy cut flowers Mr. H. C. Woodcock was first, and Mr. H. F. Porter came out first in violas, beside achieving considerable success in other sections. In the awards, the silver medal presented by the N.S.P. Society for the best bunch of sweet peas went to Dr. Curtis, Mr. Porter securing the same Society's certificate for second best. The "Electra" trophy for the member scoring the highest number of points went to Dr. Curtis with 54 points. Lady Denison-Pender presented the trophy and the Sweet Pea Society's medal and the certificate. The exhibition proved a complete success, and great credit is due to the secretary for the excellent arrangement of the exhibits. The President of the Society is Mr. J. C. Denison-Pender, and the visitors included Sir John Wolfe Barry, Sir John and Lady Denison-Pender, Sir James Pender, Sir Albert Cappel, Sir W. R. Brooke, Mr. J. G. Griffiths, Hon. A. G. Brodrick and Mr. T. W. Stratford-Andrews.

FOREIGN.

Argentina.—The "Review of the River Plate" says the National Government have sanctioned the expenditure by Santa Fé municipality of $39,285 (gold) in the erection and equipment of electricity works for lighting and power purposes in the port.

During the centenary celebrations at La Plata about 40,000 incandescent electric lamps were used for the illuminations.

Austria-Hungary.—A concession has been granted to the Aktiengesellschaft Triester Kleinbahnen (Trieste) for the construction of a light electric railway from Opcina to Sesana.

Bolivia.—A report from the Belgian Legation at La Paz states that there is every prospect that greater use will in future be made of

Digitized by Google

the abundant waterfalls and rivers in Bolivia for the generation of electric power.

Canary Islands.—The old steam tramway between Las Palmas and Puerto de la Luz, 3½ miles in length, is being electrified by a Madrid company, who have bought the concession.

China.—Consul F. E. Wilkinson (Newchwang) writes that inquiries have convinced him that there is a demand in South Manchuria for electrical goods, as in most of the large towns electric light and telephone installations are either already in existence or are contemplated. In almost every case, however, contracts are in Japanese hands.

Acting Vice-Consul Paton states that a new engine, boiler and dynamo have been ordered from the U.K. for *Mukden* (Manchuria) electricity works. The lamps used by the company are of German make. The number of lamps connected to the *Dairen* electricity supply mains is 16,000. There is a supply of power of 1,500 kw., of which the electric tramway requires 400. The present plant is unable to meet the demands upon it, and is being increased by 2,000 kw. this year. The new plant consists of American engines and generators and British boilers, rotary converters and steam condensers. The Dairen tramway system was completed and opened in September last. There are 14 miles of track. Of the cars 40 came from the U.K. and 10 from Japan, the rails from the U.K., and the motors, wires and poles from Germany. An extension of 3½ miles may be made this year.

Constantinople.—It is reported that eight offers were received for the concession for the electric lighting of Constantinople and the suburbs from the following syndicates:—

Union Ottomane, consisting of the Deutsche Bank and the Constantinople tramway group, Fouquiau & Warnant (acting for a French group), "Westinghouse" group, Cie Francaise d' Eclairage Electrique, Swiss Electrical Synd., Giros & Louchard (representing a group of French and Swiss electricians), Ganz & Co., and Schneider & Cie.

After examination by a commission of the financial standing of the various tenderers, an exhibit of their schemes will be held at the Prefecture of the City during eight days, which the public may inspect. Subsequently a technical commission (appointed by the Minister of Public Works) will examine the schemes, and within one month will send in their report indicating the most favourable tender, and also which three schemes should receive the prize of £T250. The work of installation will have to be carried out within 18 months.

Costa Rica.—The report of Consul F. N. Fox says imports to Costa Rica during 1909 from the United Kingdom and the British colonies included electrical supplies £2,453 (increase £2,356 compared with 1908) and railway material £2,260 (increase £2,005). The Guacimal hydro-electric power plant of the Abangarez Goldfields is in course of erection and will be completed early in 1911. The Costa Rica Electric Light & Traction Co. have completed and opened an extension of the San José tramways to Guadalupe, and the hydro-electric power plant at El Brazil, 9 miles west of San José, which is eventually to develop 5,000 H.P., is under construction.

Exhibition.—It is announced that the international electric railway exhibition, which was to have been opened next month at St. Petersburg, is postponed until 28th (15th O.S.) April, 1911, in order to adapt it to the 75th anniversary of the Russian railways. The exhibition will remain open three months. Inquiries to the Committee of Organisation, St. Petersburg.

France.—Vice-Consul Beresford (Cherbourg) states that it has at last been decided to convert the steam tramways to electric traction. It is also proposed to extend the tramway from Querqueville to Landemer, which will prove a great boon in opening up a charming summer resort.

The report of Consul C. Clipperton, of Rouen, for 1909 states that the Cie. Centrale de Chemin de Fer et de Tramways have applied to the Prefecture at Rouen for sanction to build at Grand-Quevilly (a suburb of Rouen) a large electrical generating plant for supply of light and power to various towns and manufacturing centres within a radius of 20/25 miles.

Holland.—The Watergraafsmeer communal authorities have decided to borrow £2,917 for extensions of their electricity undertaking.

Iceland.—A company has been formed in Norway to utilise the water power of the Gullfoss and Sog Falls for the generation of electrical energy.

Italy.—The Minister of Posts and Telegraphs has brought forward a Bill for the construction of a large number of new telephone lines for intercommunication throughout the country, at an estimated cost of £29,600, of which £2,400 is to be set apart for apparatus and material for experiments in multiple telephony and in combined telephony and telegraphy.

The Public Works Department are about to spend £17,200 upon electric cranes for the new port on the river Tiber, near the Rome-Pisa railway line. (Only firms on the Government list are usually allowed to tender.)

The report of Consul Maclean (*Sicily*) for 1909 states that new iron and steel works will be erected at Palermo by the Soc. Anon. Ferri e Metalli during the present year.

The power required in the works will be 12,000 H.P., and all the accessory machinery will be driven by electric power. A Belgian company with £200,000 capital was formed in Brussels in August last to construct and work a tramway from Palermo to Mondello.

Consul-General Keene (*Genoa*) states that the electric tramways (which are owned by a company) ran 7,951,810 car-miles during 1909 and carried 61,152,935 passengers. The total receipts were £320,786 and the gross profits £108,829. There are 94 miles of tramways, and the companies employ 1,555 persons.

Consul Guattari (*Savona*) says the Italian State Railways Department have decided to extend the electrification of the Savona–San Guiseppe railway as far as Ceva, and that the total length of the electric line will be 28 miles.

A 30 years' concession for the construction and working of an electric tramway from Savona to Vado has been granted by the Consiglio Provinciale of Genoa to a local committee interested in the formation of a company, with a capital of about £32,000, to carry out the work. It is expected that the line will be completed by the end of 1911.

Vice-Consul E. Antione (*Turin*) states that tramways owned and worked by two companies represent a total length of about 65 miles.

Liberia (West Africa).—There is little to record of an electrical character from this independent negro Republic, and that little is chiefly of a negative character, but a few extracts from Vice-Consul M. Y. H. Park's report may be of interest as indicating the undeveloped condition of the country.

There are no local telegraph or telephone systems yet. Direct cable communication with Europe was established by German cable, via Teneriffe, on March 21, 1910. There are no railways, and all transport is done by native carriers. There are no roads, but the interior is intersected by numerous tracks, some of them barely a foot wide. Rubber is the principal industry, but it is as yet in its infancy. Scientific instruments, machinery and mining tools and "Faulkner's telephone, &c., materials" may be imported duty free.

Mozambique.—Consul Maugham states, in his report on the province of Mozambique for 1909, that Germany is the more successful competitor in the supply of machinery and electrical and telegraph material, owing to well undertaken local representation not enjoyed by most British manufacturers in those branches.

In regard to electrical apparatus and railway and telegraph material, Mr. Maugham is satisfied that the outlay of the various departments of the administration of the province for local use would repay a system of combined representation of manufacturers. At present there is no such thing as serious British competition, while Continental manufacturers are so keenly represented that the bulk of the orders is without difficulty obtained for them. The rule in inviting tenders is to invite a number of local agents to send in estimates, and very frequently an order is given at once, without formality, and, naturally, goes to the local business house whose representative can produce the goods at the shortest notice and at the same time give evidence of possessing an intelligent knowledge of the requirements of the moment. Mr. Maugham offers to furnish further information on the subject to British manufacturers. Imports at Lourenço Marques in 1908 included electric and telegraph material £1,543, compared with £1,320 in 1907 and £1,918 in 1906. Of this total Germany supplied £679 and the U.K. £647.

Peru.—The report of Consul-General L. J. Jerome for 1908-9 says the Peruvian Telephone Co. has spent £50,000 during the last two years in changing its service in Lima from overhead to underground, and that the common battery system has been adopted. The average subscription in Lima is £7. 10s. and the number of subscribers in the city is 1,600. The total telephone system connecting the various sections of the country may be taken at 3,000 miles.

The effect of the service of electric tramways running between Callao and Lima has proved very great. Mercantile houses which formerly maintained considerable branch establishments at Callao have removed to Lima. In the evenings the tramcars are crowded.

Acting Vice-Consul Rowlands at Mollendo says there is a general tendency to increase the use of electricity for power and lighting in Arequipa and in the mines. The Societe Electrique de Arequipa, which was formed about five years ago and is under Peruvian management, is working hard to secure an increased demand for electricity for public and domestic purposes. There has been a movement towards replacing the existing horse tramways at Arequipa by electric tramways, but, although a quantity of material arrived in January, 1909, work has not yet been commenced.

Portugal.—Vice-Consul P. dos Santos says the municipalities of Faro and Loulé are "sanctioning the construction on their own account of electric cars for passengers and goods," and "they are trying to furnish the two chief towns of Faro and Loulé with electric light."

Spain.—The following items of news are forwarded by the British Consuls in Spain:—

Consul Arthur Keyser (*Seville*) writes that electricity is being introduced to lighten labour on farms, more especially for the turning

Digitized by Google

of the heavy wheels which draw the water supply from wells. The German electricity company continues to enjoy a monopoly of providing electric power for Seville, and has obtained control of the power from La Hidrö Electrica del Guadiaro. Imports at Seville in 1909 included dynamos 85 tons (British 3 tons) compared with 195 tons (British 2 tons) in 1908.

Vice-Consul W. J. Smith (*Algeciras*) writes that an English firm has set up a new electric lighting installation and competition is proving a great benefit to the town.

Vice-Consul R. E. Carr (*Cordoba*) states that serious efforts are being made to induce foreign capitalists to construct electric tramways, and the local authorities are making a broad street into the heart of the city to accommodate tramways.

Switzerland.—A concession has been granted to Messrs. Isler, Cathrein & Roemer for the construction and working of a narrow-gauge electric railway from Brigue via Riederalp and Eggishorn to the Aletsch Glacier, at an estimated cost of 3,850,000 fr. (£154,000). A concession has also been granted to Messrs. Baumgartner, Beusch, Bohl, Hardegger, Kuhn & Looser for a similar line from Buchs to Nesslau, the estimated cost of which is 5,100,000 fr. (£204,000).

Turkey.—The report of Consul H. E. Satow (Palestine) says the construction of an electric tramroad at Jaffa has been mooted, but nothing has been done so far to carry it out.

Consular Agent Knesevich states that at Gaza there is talk of granting a concession for an electric tramway from the eastern side of Gaza to the sea shore, and plans have been drawn up.

Consul Devey (Damascus) says the electrical plant in the Kadem workshop of the Hejaz Railway was installed in Jan., 1909, and repairs have been made to upwards of 20 engines, and about 200 wagons and carriages. The average monthly takings on the electric tramways were £980 (compared with £820 and £790 in 1908 and 1907 respectively). Some small extensions are about to be made, and the question of securing land for extensions to Muzzel Kassab and to Duma (6 miles north of Damascus) is under discussion. In Dec., 1909, the record receipts of £700 for electric lighting were reached. Nearly 1,300 houses are now lighted electrically, the average number of lamps being 10 per house. The power supply to the Hejaz workshops produces £1,280 per annum, and electric power for four or five other workshops has been applied for.

Vice-Consul E. C. D. Rawlins (Adana) says a concession is offered for electric tramways and the supply of electricity for lighting in Adana, and that similar schemes might be worked out for Tarsus and Mersina.

A company called the Popular Cartagena is being formed, with a capital of 500,000 pesetas (£18,500), for the erection of an electric power station of 450 kw. capacity for supply of continuous current for lighting and power in Cartagena.

ELECTRICITY SUPPLY AND TRAMWAY ACCOUNTS.

Acton.—The district auditor (Mr. Sutherland Wilkinson) has reported to the Council on the accounts for the year ended March 31.

The report states that a great improvement has been made in the financial position of the electricity undertaking. The deficit on the net revenue account at March 31, 1909, was £4,943. 17s. 10d., which was met by a transfer from the district fund, while the deficit at March 31, 1910, was only £675. 1s. 2d. The improved result was accounted for (1) by a reduction in expenditure of some £1,492. chiefly in cost of generation and distribution, and (2) by an increase in income of £2,913. chiefly due to increased sales of current and to a charge being made for hire of meters not previouslay mde. The expenditure chargeable on net revenue account increased by £137.

Barnstaple.—The capital expended on the electricity department at March 31 was £32,185, an increase of £456.

Income from the sale of current was £4,157 and total receipts £4,412. Expenses were £3,000 and gross profit £1,412. After paying interest (£892), instalments of principal (£974), and interest on overdraft (£106), there was a deficit of £560 on the year. 236,382 units were sold (against 221,059 in 1908-9), including 157,142 to private consumers (against 126,887), and 79,240 for public lighting (against 94,172). There are 30 arc and 174 Osram lamps for public lighting, and the total maximum supply demanded was 248 kw.

Birkenhead.—The income of the Electricity department for the year ended March 31 was £21,410, including £20,459 from the sale of current.

Expenses were £8,927, and after paying interest (£4,343), sinking fund (£3,809), &c., and contributing £1,000 to relief of rates the balance (£2,963) was placed to renewals fund. The capital expended is £157,479, an increase of £6,789.

The income of the tramways department was £56,817, including £55,759 for traffic receipts. Working expenses were £33,757, and after allowing for bad debts., &c., the balance was £22,683. Interest on capital and on amount applied to redemption of debt, &c., absorbed £11,768, and sinking fund £9,317. The balance profit (including £780 returned for income tax over-paid) was £2,357. 6s. 11d., which has been placed to renewals fund. The capital expended is £366,419, an increase of £2,990 during the year.

Doncaster.—It was reported to the Corporation last week that the profit on the electricity department during the past year was £1,222, which has been carried to renewal fund; but on the tramways there was a deficit of £134. 14s. 10d., against £1,477 in 1908-9.

ELECTRICITY SUPPLY TABLES AND DATA.

This Valuable Set of Tables and Engineering Data relating to Electricity Supply and to Electric Traction on Railways and Tramways in the United Kingdom, the Colonies, and some important places abroad, is now ready, and can be obtained complete in handy book form, price 6s. 6d. post free, or on very hard paper for rough or constant use, price 8s. 6d. post free. A complete Index is included.

Ilford.—During the year ended March 31 the profit on the electricity department was £1,562, against a deficit of £300 in 1908-9.

The improved result is mainly due to a saving in coal effected by the use of chain grate stokers.

The chairman of the Electricity committee (Coun. PHILPOT), said the gross profit amounted to £12,865, or over 8 per cent. on the capital. They had now a reserve fund of £8,000, and they had repaid £30,000 of the capital. The private lighting demand had gone up by 93,000 units in spite of the extended use of metal filament lamps, and they had also supplied 26,000 more units for power. There had been a falling off in the current supplied to the tramways.

Maidstone.—The accounts of the electricity supply department for the year ended March 31 show total income £13,281, against £13,308 in 1908-9.

The working expenses were £7,625 (against £7,364), and the gross profit was £5,657 (against £5,944). After paying interest (£2,313) and sinking fund (£3,294) there was a deficit of £102. There was an increase in the receipts from the sale of current for public and private lighting, and the drop in the total receipts was due to decreased consumption by the light railways department. The capital expended is now £81,010, an increase of £2,231 during the year.

Sheffield.—During the year ended March 25 the municipal tramways department carried 78,620,798 passengers and 7,459,911 car-miles were run. The income was £299,154 and the gross profit £117,637. After meeting all charges the net balance on the year's working was £39,252, of which £12,192 is to be applied to relief of rates, £21,605 placed to renewals fund, £2,000 to special purposes fund and £3,453 to accumulated surplus fund. The capital expenditure is £1,203,326.

At the meeting of the Corporation on Wednesday, Ald. Bennett in submitting the accounts of the electricity department for the past year, said that it was a matter for regret that more satisfactory accounts could not be presented, but there was not the slightest doubt that the adoption of metal filament lamps had been a set-back which they, along with every other electricity undertaking in the kingdom, had suffered from. If it had not been for the loss on that account, there would have been a profit of £4,808, instead of a deficiency of over £2,000. They hoped that next year there would be no loss. In reply to questions, he said that if they had not had to meet the interest and sinking fund on unproductive capital, there would have been a profit of £9,060 or £10,060. The lighting and heating accounts had not been kept separately, but the matter should have attention.

Southport.—The borough electrical engineer (Mr. A. S. Black) reports that there was a net profit of £1,475 on the past year's working of the electricity department, despite the decrease of £3,100 in revenue owing to the extended use of metal filament lamps.

Wimbledon.—The accounts of the electricity department for the year ended March were presented to the Council last week by the chairman of the Electric Light committee (Councillor D. Stuart).

Mr. Stuart said it was gratifying to again have a surplus, which amounted to £1,986. 3s. 5d., against £2,510 in 1908-9. Receipts from sale of current by meter were £23,499, and the total income was £28,920. Total expenses were £12,827 (1·392d. per unit, against 1·502d.) and gross profit was £16,093. After paying interest (£5,943), sinking fund (£742) and instalments of principal (£7,422), the net profit was £1,986 odd. 3,052,933 units were generated and 2,211,933 sold; 1,709,513 units were sold to private consumers (at an average price of 3·291d. per unit) and 502,420 supplied to public lamps (at 2·519d.). There are 91 arcs and 1,136 metal filament lamps for public lighting. Consumers numbered 3,252 in Wimbledon and 625 in Merton, and the total lamps connected were equivalent to 183,028 35-watt (including 3,567 for street lighting). The total maximum supply demanded was 1,344 kw. The existing debt was £168,999. 18s. 4d., an increase of £1,524. The gross earnings were 17·1 per cent., and the net earnings 9·52 per cent. The reserve fund stood at 7·56 per cent., and if the £2,024 standing to suspense account is added it would be 8·77 per cent. of the existing debt. Generating expenses were going down, but there was a slight increase in the cost of distribution. The total cost of generation was 0·830d. per unit, against 1·035d.

Wolverhampton.—At the Corporation meeting on Monday the chairman of the Electricity committee (Mr. Gough Allen) moved the adoption of the annual report and accounts.

He said that it was by far the best report they had issued. They had made a gross profit of £20,059, against £15,891 in 1909; and the net profit was £8,297, against £3,411. Twelve months ago the committee reported that the undertaking had been adversely affected by trade depression and the use of metal filament lamps. There had since been great improvement, and the large increase in the current sold seemed to show that trade depression was passing away. The cost of generating had gone down, and the undertaking was in a sounder position than ever.

TRADE NOTES AND NOTICES.

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK.—The 1910 Edition of the Big Blue Book is NOW READY, price 15s., post free in the United Kingdom, 15s. 9d. The volume brings a great mass of very valuable statistical and technical data quite up to date, and the Directorial Division has been thoroughly revised and amplified up to February 16th.

All branches of Electrical Engineering and Industry are fully treated, and Electro-Financial matters receive every attention in the new volume, which aggregates more than 2,000 pages. The Directory Division is complete and thoroughly accurate, and has been completely revised. The Big Blue Book contains more names of live electrical firms and persons than any other Directory published, and this notwithstanding that all mere lists of members of Societies and Institutions (so easily and cheaply available) are excluded, as unreliable and of little value for Manufacturers' and Dealers' purposes. The full set of valuable Statistical and Engineering Tables, &c., have been very carefully revised and extended, and are now issued in a handy form. These are included in the 1910 Big Blue Book, making it the most complete work of the kind ever published.

TENDERS INVITED.

BELFAST Harbour Commissioners invite tenders for supply and delivery into the Alexandra Graving Dock engine house, Belfast, of of 3¼ miles of 7/18 paper insulated lead-covered h.t. cable, served with jute, and suitable for 3,000 volt continuous current; also ½ mile 7/18 rubber insulated cable to sample. Specification, forms of tender, &c., from the harbour engineer, Mr. W. Redfern Kelly, M.Inst.C.E. Tenders to the secretary, Mr. W. A. Currie, Harbour Office, Belfast, by 27th inst. See also an advertisement.

BELFAST Harbour Commissioners also invite tenders for the construction, delivery and erection at their electric light station of an independent surface condensing plant, with oil separator, &c. Specification and form of tender, &c., from the harbour engineer, Mr. W. Redfern Kelly, M.I.C.E., and tenders addressed to the secretary, Mr. W. A. Currie, Harbour Office, Belfast, must be in by Wednesday, July 27. See also an advertisement.

Tenders are invited up to Sept. 7 for supply of battery material and glassware to the Postmaster-General's Department in QUEENSLAND. Tender forms and specifications from the Official Secretary in Great Britain of the Commonwealth of Australia, 72, Victoria-street, London, S.W. See also an advertisement.

LONDON County Council want tenders by 11 a.m. July 26, for supply of 4,800 steel tyres for driving wheels, and 1,600 steel tyres for pony wheels for tramcars. Forms of tender, &c., from the Chief Officer.

LONDON County Council also want tenders by 11 a.m., July 19 for the roadwork and platelaying required for the construction of tramways in Battersea Bridge-road and Beaufort-street, Chelsea, on the underground conduit system, and for paving work. Specifications, &c., from the Chief Engineer, Spring-gardens, S.W.

WALTHAMSTOW Council want tenders by noon July 22 for supply and fixing of a railway weighbridge at the siding adjoining the electricity works, also for car bodies, trucks and electrical and magnetic brake equipments for six double-deck roof-covered tramcars. Specifications, &c., from the Electrical and Tramways Engineer, Priory-avenue, Walthamstow.

WHITEHAVEN Corporation want tenders by July 16 for supply of a 35 kw. single field d.c. automatic converter to convert from 420 to 220 volts d.c., and two sprinkler type mechanical stokers for Babcock boilers. Specifications from Borough Electrical Engineer.

LEITH Corporation require tenders by noon July 25 for supply and erection of 500 kw. mixed pressure turbine and d.-c. generator, condensing plant and cooling tower. Specification, &c., from the Burgh Electrical Engineer.

MORECAMBE Corporation want tenders by July 28 for feeder pillars and arc lamp carbons. Specifications, &c., from the Borough Electrical Engineer.

CHELMSFORD Education committee want tenders by Aug. 31 for electric light wiring at Trinity-road school. Forms, &c., from Mr. W. H. Pertwee, London-road, Chelmsford.

SALFORD Corporation require tenders by noon July 18 for a borehole pumping plant for their electricity works, Pendleton. Particulars from the Borough Electrical Engineer.

MANCHESTER Tramways committee want tenders by 10 a.m. July 19 for supply of h.d. copper trolley wire. Specification, &c., from Mr. J. M. McElroy, 55, Piccadilly, Manchester.

BARNET Guardians want tenders by July 26 for supply of dynamos, motors, battery, wiring work, &c. Tender forms from the clerk.

Tenders are invited up to Aug. 2 for the supply and delivery of 1,820 private letter box fronts to the Postmaster-General's Department in the States of VICTORIA, QUEENSLAND, SOUTH AUSTRALIA and WESTERN AUSTRALIA. Tender forms and specifications from the Commonwealth Office, 72, Victoria-street, London, S.W.

Tenders are invited up to July 27 for supply of a pneumatic tube service to the Postmaster-General's Department at ADELAIDE (S. Australia). Tender forms and specifications from the Commonwealth Office, 72, Victoria-street, London, S.W.

The Deputy Postmaster-General, MELBOURNE (Victoria), will receive tenders until 3 p.m. Aug. 30 for supply of electrical sundries, insulators, wire and sulphate of magnesia. Local representation necessary. Further particulars from 72, Victoria-street, London, S.W.

The TRANSVAAL Administration of Posts and Telegraphs require tenders for supply of 2 miles of 64-conductor switchboard cable. Further information from 72, Victoria-street, London, S.W. Tenders to Pretoria by July 27.

Firms having agents in Canada whom they can instruct by cable will be in a position to tender for portion of a contract for the supply and erection of an electrically-driven centrifugal pump and automatic starter required by the City Corporation of Moose Jaw, Saskatchewan, Canada. Plans and specifications are to be seen at the office of the City Engineer, Moose Jaw, and tenders are to be sent by 8 p.m. on July 18 to Mr. W. F. Heal, the city clerk. Plans and specifications are also to be seen at 62, Church-street, Toronto; B33, Board of Trade-buildings, Montreal; and Room 424, Building Exchange-building, Winnipeg. The other portion of this contract (B) is for supply and erection of a complete air lift system.

The Turkish Ministry of Commerce and Public Works want tenders by Oct. 28 (Nov. 10) for a concession for the construction and working of electric tramways in CONSTANTINOPLE and suburbs. A deposit of £13,500 (sterling) is required with each tender. Local representation is essential. Copy of specification (in French) may be seen at 73, Basinghall-street, London, E.C.

The Société Nationale des Chemins de fer Vicinaux, BRUSSELS, want tenders by July 20 for underground cables, and by July 27 for the equipment of a transformer station.

The Ministerio de Fomento, MADRID, will receive tenders until July 30 for the construction of an electric (or steam) strategic railway from Requena to Alcaráz, via Casas Ibáñez and Albacete. The contract is open to Spanish firms only.

TENDERS RECEIVED AND ACCEPTED.

L.C.C. are recommended by the Fire Brigade committee to accept the following tenders for wiring and fitting fire brigade stations for electric lighting:—

G. Weston & Sons (lowest), for Woolwich station £185. (Five tenders received; highest £270. Chief engineer's estimate £170.)

W. J. Fryer & Co. (lowest), for Kingsland station, £164. 18s. 6d. (Five tenders; highest £221. Chief engineer's estimate £182.)

Tilley Bros. (lowest), for Lewisham station, £160. 18s. (Five tenders; highest £234. Chief engineer's estimate £189.)

West Bromwich Corporation are recommended to accept the tender of the British Insulated & Helsby Cables for supply and laying of paper insulated lead-covered feeder and pilot cables.

The following firms also tendered: Callender's Cable & Construction Co., Lahmeyer Electrical Co., W. T. Henley's Telegraph Works Co., W. T. Glover & Co., Western Electric Co., Siemens Bros. & Co. and Johnson & Phillips.

Stretford Council has accepted the following tenders:—

British Westinghouse Co., three-wire booster (£859) and safety attachment (£51); Worthington Pump Co., condensing plant (£1,180); James Hodgkinson, one pair coking stokers (£132. 10s.); E. Green & Sons, additional economiser tubes (£110).

Sheffield Council has accepted the following tenders:—

J. Spencer (Ltd.), 26 No. 1 tramway poles with fittings, £6. 11s. 6d. each, and seven No. 2 ditto, without fittings, £8. 14s. 3d.; Hadfield's Steel Foundry Co., points and crossings for Shoreham street tramway depot, £954. 10s.

Erith Council have accepted the tender of Fraser & Chalmers for a 1,000 kw. Rateau impulse turbo-alternator at £4,305, and for a Lancashire boiler at £1,200; and that of the British Westinghouse

Digitized by Google

Co. for a stator at £264. There were seven tenders for the turbo-alternator and twelve for the boiler.

Stockport Council have accepted the following tenders :—

Consolidated Electric Works & Appliances Co., 30, tramcar destinator screens; Mitchell's Emery Wheel Co., grinding machine; Ferranti Limited, meters.

Hammersmith (London) Electricity committee have accepted, after testing the specimen prepayment meters submitted by seven firms and considering the Engineer's report upon them, the tender of Ferranti Ltd. at £3 for all sizes and for 110 and 220 volt circuit.

Nine firms submitted tenders to the Council for the supply of one 200 kw. transformer :—

British Electric Transformer Co. (*accepted*), £159. Spagnoletti (Ltd.) £168, General Electric Co. £171, British Thomson-Houston Co. £175, British Westinghouse Co. £190, Johnson & Phillips £190, Lahmeyer Electric Co. (oil cooled, not to specification) £172. 10s., Union Electric Co. £118. 10s., Ferranti (Ltd.) £128. 10s.

Messrs. Jens Orten-Böving & Co. have received an order from the British North American Pulp Co. for six Francis turbines of 1,600 H.P. each, and 1,800 H.P. for overload for their Ocean Falls plant in British Columbia.

Herne Bay Council have accepted the following tenders :—

Harpin & Co., 900 ft. second hand strip cable for suspending incandescent lamps, 7d. per foot; Siemens Bros. & Co., cable for lighting pier pavilion, £60; Union Electric Co., 10 flame lamps, £60.

Bolton Council have accepted the tender of the Brockie-Pell Arc Lamp for the supply of single-phase transformers for 12 months in sizes up to 15 k.v.a.

Bolton Corporation have also placed an order with Ed. Bennis & Co. for two sprinkler stokers and self-cleaning compressed air furnaces for a new Lancashire boiler at their electricity works.

Croydon Corporation have accepted the tender of Johnson & Phillips for wiring the extensions at the Borough Hospital for £349. There were 26 tenders, varying from that of the accepted to £785.

Walsall Council has accepted the tender of Herbert Morris & Bastert for an overhead hand-power travelling crane and gantrey at Darwall-street sub-station.

Spennymoor Council have accepted the tender of the Northern Counties Electricity Supply Co. for lighting 302 public lamps at 52s. each per annum.

Tonbridge Council have accepted the tender of Galloways (Ltd.) for a Lancashire boiler, economiser extensions and pipework at £574.

The Bastian Meter Co. have secured the contract for the supply of meters at Bolton,

Brandon Council have accepted the tender of F. Reid, Ferens & Co. for electric lamps and fittings for the hospital and lodge at £33.

Canterbury Council have accepted the tender of G. E. Dashwood for electrical work for six months.

Brighton Council have accepted the tender of Siemens Bros. & Co. for 250 yds. of 1 sq. in. cable at £416.

Belfast Guardians have accepted the tender of Wm. Dowling for erection of a power house at £1,200.

Coalville Council have accepted the tender of Blythe Bros. for the erection of electric fire bells at £66.

Browett, Lindley & Co. recently received an order for two 325 B.H.P. engines for the Mount Elliott Copper Mines, Queensland.

Reading Council have accepted the tender of W. H. Baughan & Co. for wiring work at the library at £84.

Launceston (Tasmania) Tramways committee have accepted the tender of the Brush Co. for tramcar trucks, £1,122; the Australian General Electric Co. for motor equipments, £3,206, and Hadfield's Steel Foundry Co. for points and crossings, £2,120.

Electrically-driven Motor Vans.—At the meeting of London County Council on Tuesday the Fire Brigade committee submitted a report on the tenders received for the supply of three electrically-driven motor (escape) vans. The tenders were :—

Electric Vehicle Co., £825 each; Merryweather & Sons, £947. 16s. 8d. each (including £91 for Tudor batteries and £280 for spares); "Cedes" Electric Traction Co., £1,044. 18s. 11d. each (including £380. 9s. 3d. for spares); H. Simonis & Co., £1,046 each; Crompton & Co., £1,048 each (including £66 for Tudor batteries).

Up to the present, the report states, no electrically-driven appliances have been purchased for use by the London Fire Brigade, although such appliances have for some time past been in successful operation in the principal cities of Europe. The first cost of electrically-driven was somewhat higher than that of petrol-driven appliances, but the wear and tear were less, and this was to be expected if new batteries were provided from time to time. The chassis and motors should last much longer than those of petrol-driven appliances. Having carefully considered the tenders, the committee were of opinion that the interests of the Council would be best served by the acceptance of the tender of "Cedes" Electric Traction Co., owing to the special type of vehicle offered by the company and the wide experience possessed by it in that class of work. The company proposed to sublet the supply of the chassis and wheel motors to the Austrian Daimler Motor Co., and the supply of the batteries to the Tudor Accumulator Co. The committee recommended that three vehicles be obtained from the "Cedes" Co., but consideration of the matter was postponed.

Ship Lighting.—Messrs. W. C. Martin & Co., Glasgow, have received orders from Messrs. Swan, Hunter & Wigham Richardson to supply and fit electrical installations for the two new steamers building for the Cunard Company. The installations will have a large number of lights and motors, and will be fitted similar to the equipment supplied by the same firm for the "Mauretania." Messrs. Martin & Co. have also contracted to supply the electric installation for the new Anchor Liner "Cameronia," and several of the new steamers recently ordered for the British India Steam Navigation Co., two steamers for the Harrison Line of Liverpool, a large passenger liner for Italian owners and other vessels, making a total of electrical plant in hand of over 2,000 H.P.

"Nesdrum" Boilers and the Admiralty.—Messrs. Richardsons, Westgarth & Co., Middlesbrough, have received intimation from the Admiralty that their name has been placed on the Admiralty list of approved water-tube boiler makers.

Commonwealth Tenders.—The Public Works Department (N.S.W.) have accepted the tender of Standard-Waygood (Ltd.) for supply of an electric goods lift for the General Post Office, Sydney.

The Postmaster-General's Department (N.S.W.) have accepted the tenders of the Western Electric Co. for supply and erection at Sydney telephone exchange of two incoming junction sections of common battery switchboard at £2,050; F. Zwicker & Co. for 26,000 porcelain insulators at 3½d. each; and Jas. Paton & Co. for 4,000 porcelain insulators at 3d. each.

BUSINESS NOTICES.

Owing to the rapid increase in their business as lift manufacturers, Messrs. Smith, Major & Stevens have found their Battersea premises inadequate, and are taking new works, which are now in course of erection at Northamptan.

It is hoped that the new works, which will be equipped on up-to-date principles, will be ready for occupation in the autumn. A portion of the staff and a number of workmen will be retained in London, where they and their predecessors have been established for 140 years.

Mr. C. M. Ferguson notifies us that the agreement under which Messrs. J. Gordon & Co., 81, Knightrider-street, London, E.C., acted as selling agents for his sectional steam superheater has expired, and arrangements have been made for all future business connected with the superheater to be carried on at 11, Queen Victoria-street, E.C., under Mr. Ferguson's personal supervision.

Messrs. W. F. Dennis & Co. have been appointed sole agents in the United Kingdom for the Karlsbader Kaolin Industrie Gesellschaft (of Merkelsgrün Austria), manufacturers of telephone, telegraph and high tension porcelain insulators and other porcelain goods for electrical purposes.

Messrs. A. Hirst & Son (Ltd.), makers of the Crescent coal cutters and coal drills have settled down in their newly erected works in Meadow-lane, Dewsbury. The premises are constructed to allow of considerable expansion when necessary.

The change had to be made on account of the increasing demand for the firm's specialities, and at present there are numerous orders in hand for Crescent coal cutters.

Sale by Auction.—Messrs. Horne & Co., 35, Old Queen-street, Westminster, S.W., will sell by public auction at the Royal Arsenal, Woolwich, on Thursday, July 21, at 11 a.m., unserviceable and obsolete stores, including quantities of iron and steel, brass, copper, gunmetal, lead and antimony, zinc, &c., some cable drums, lathes and machine tools, electric light fittings, telegraph and electrical instruments, &c. The flots may be viewed at the Royal Arsenal, Woolwich, on Monday, Tuesday and Wednesday, previous to and on morning of sale. Catalogues from the War Office, Whitehall; the Ordnance Office, Tower; and the Ordnance Office, Royal Arsenal, Woolwich. See also an advertisement.

Plant for Sale.—Two gas driven alternator sets of 250 kw. each are advertised for sale.

Agent Wanted.—A German firm manufacturing watertight electrical appliances requires an agent to sell goods on commission.

Patents Development.—The owners of British Patent No. 23,378 (1907), for "Improvements in the manufacture of electric resistances," desire to sell their patent rights or to grant licences. Applications to Messrs. Day, Davies & Hunt, 321, High Holborn, London, W.C.

Digitized by Google

The owner of Patent No. 16,729/1906, relating to "Dynamo electric generators," desires to arrange by licence or otherwise for manufacture and for the commercial development of the patent. Address Messrs. Herbt. Haddan & Co., 31 and 32, Bedford-street, Strand, London, W.C.

The proprietor of letters patent No. 28,542/1907, relating to "Electrical induction furnaces," desires to enter into arrangements for exploiting same. Communications to Messrs. J. E. Evans-Jackson & Co., 19 and 20, Holborn Viaduct, London, E.C.

The proprietors of patent No. 5,203/1907, relating to "Brush carriers of electric machines," and No. 17,698/1907, relating to "Commutators and brush carriers of electric machines," desire to enter into negotiations for the grant of licences to manufacture under royalty. Applications to Messrs. Carpmael & Co., 24, Southampton-buildings, London, W.C.

"Green Book of London Society."—From Messrs. J. Whitaker & Sons, London, we have to acknowledge receipt of a copy of this book, which forms a directory of the court, society and political and official world of the United Kingdom. Besides giving a quantity of information on matters affecting literature, art, science, sport, the drama and many other subjects, those who have occasion to refer to works of reference of this nature will find the book so well arranged that the information it gives can be turned up with facility. There is included a list of foreign titles borne by British subjects—in fact, much of the information here available is that which is omitted from many other books of a like nature. The published price of the "Green Book" is 5s. net.

The Holiday Season.—Our readers are reminded that the Great Central Railway (Publicity Dept., 216, Marylebone-road, London, N.W.) have ready their A B C Programme of holiday arrangements, which can be obtained free by request. Much information concerning the numerous holiday and rest resorts on the company's extensive system, for which specially low fares are quoted, are set out in the programme.

CATALOGUES, &c.

"Freezor" Electric Fans.—We have received from the General Electric Co. a copy of their new catalogue dealing with this seasonable subject. It is prefaced by a general description of these apparatus which is followed by details, electrical, mechanical and financial, of the various types of desk, ceiling and exhaust fans, as well as of that very useful apparatus the "Bandy" punkah. The fans are made in all sizes and are also designed to suit all pockets.

Models.—Two catalogues are to hand from Messrs. Bassett, Lowke (Ltd.), which deal with model aeroplanes and small aeroplane motors, and model yachts and electrically operated model torpedo boats, warships, Atlantic liners, &c. Some of the latter are most elaborate and are listed as high as £45. All the models are to scale.

Imports.—The following are official values of electrical machinery, material and apparatus imported into this country (*a*) during June, 1910, and (*b*) during the current year from Jan. 1 to June 30, with the increases or decreases compared with the corresponding periods of 1909:—

Electrical machinery (*a*) £46,350 (increase £4,806), (*b*) £279,432 (increase £46,665); telegraph and telephone cables (*a*) £11,168 (decrease £10,437), (*b*) £72,447 (increase £9,772); telegraph and telephone apparatus (*a*) £14,424 (decrease £3,310), (*b*) £89,102 (decrease £3,753); other electrical wires and cables, rubber insulated (*a*) £30,323 (increase £23,113), (*b*) £99,315 (increase £70,279); with other insulations (*a*) £1,738 (decrease £6,693), (*b*) £14,575 (decrease £39,233); carbons (*a*) £10,173 (decrease £693), (*b*) £68,033 (increase £2,346); glow lamps (*a*) £41,755 (increase £9,751), (*b*) £269,565 (increase £52,327); arc lamps and electric searchlights (*a*) £252 (decrease £29), (*b*) £1,801 (decrease £7,025); parts of arc lamps and searchlights (other than carbons) £5,395 (decrease £86), (*b*) £35,643 (increase £7,916); primary and secondary batteries (*a*) £3,233 (decrease £97), (*b*) £20,571 (decrease £3,962). Total of electrical goods and apparatus, other than machinery and telegraph and telephone wire (*a*) £128,295 (increase £11,726), (*b*) £720,827 (increase £86,289).

Exports.—The exports of electrical machinery, material, &c. (*a*) during June, 1910, and (*b*) during the current year from Jan. 1 to June 30, and the increases and decreases compared with the corresponding periods of 1909, are as follows:—

Electrical machinery (*a*) £150,710 (increase £22,863), (*b*) £719,423 (increase £11,762); telegraph and telephone cables (*a*) £29,773 (increase £18,624), (*b*) £900,094 (increase £701,666); telegraph and telephone apparatus (*a*) £16,104 (decrease £12,813), (*b*) £81,967 (decrease £41,527); other electrical wires and cables, rubber insulated (*a*) £26,983 (increase £10,366), (*b*) £199,363 (increase £72,586); with other insulations (*a*) £30,987 (decrease £11,857), (*b*) £144,496 (decrease £3,143); carbons (*a*) £1,249 (increase £410), (*b*) £8,662 (increase £4,462); glow lamps (*a*) £11,322 (increase £5,701), (*b*) £62,817 (increase £27,597); arc lamps and searchlights (*a*) £1,654 (increase £554), (*b*) £9,420 (decrease £125); parts of arc lamps and searchlights (other than carbons) (*a*) £1,028 (decrease £122), (*b*) £6,739 (decrease £1,711); primary and secondary batteries (*a*) £11,849 (increase £1,552), (*b*) £53,166 (decrease £3,332). Total of electrical goods and apparatus, other than machinery and telegraph and telephone wire (*a*) £168,166 (increase £21,623), (*b*) £1,692,794 (increase £807,158).

BANKRUPTCIES, LIQUIDATIONS, &c.

Frank Sheppard, electrician, 4, Haslett-road, Kensington, London, has been adjudicated bankrupt.

A receiving order has been made against Ernest Albt. Thorn, electrical engineer, &c., 22, Mossbury-road, Clapham Junction, London, S.W. First meeting of creditors July 21 at 132, York-road, London, S.E. Public examination Aug. 4 at the Court House, Wandsworth, S.W.

An application for the discharge of Geo. K. Spivey, formerly electrical engineer, Market-place, Wakefield, and Bradford-road, Batley Carr, will be heard on Aug. 9 at the Court House, Wakefield.

A dividend is to be paid to creditors of Alan McAlpin (trading as McAlpin & Co.), electrical engineer and contractor, 44, Cank-street, Leicester, and Cumbergate, Peterborough. Claims to Mr. L. V. Wykes, 24, Friar-lane, Leicester, by July 25.

A meeting will be held on Aug. 9 at Broad-street House, London, E.C., to receive an account of the winding up of the Britannia Electric Lamp Works (1905), Ltd.

The Alliance Electrical Co. (Ltd.) is being wound up voluntarily for purposes of reconstruction. Mr. H. Marriott is liquidator. The liquidation is solely for the purpose of a re-arrangement of capital, and all creditors will be paid in the ordinary course at the company's offices, 23, Grafton-street, London, W.

Deed of Assignment.—A dividend is to be paid under a deed of assignment executed by W. P. Theerman (trading as W. P. Theerman & Co.), electrical engineer, 263, Oxford-street, Manchester. Claims to Mr. G. E. Cor field, Balfour House, Finsbury-pavement, London, E.C., or to Mr. P. Gregson, 44, Brown-street, Manchester, by July 16.

COMPANIES' MEETINGS AND REPORTS.

Electric Construction Co. (Ltd.)

The seventeenth annual general meeting of this company was held yesterday (Thursday), under the presidency of Mr. Walter S. B. McLaren, M.P.

The SECRETARY (Mr. David Willock) having read the notice convening the meeting and the auditors' report,

The CHAIRMAN said: Gentlemen, the accounts we submitto-day, while not so favourable as we anticipated at this time last year, are not unsatisfactory having regard to the conditions which have prevailed. I told you at our last general meeting that volume of business was the crux of the situation, and I am sorry to say that our hopes of maintaining the larger output of last year have not been fulfilled. However, there are not wanting many indications that the effect of the introduction of metal filament lamps is now passing away, and this, coupled with the general improvement in trade, justifies us in expecting a greater demand for electrical machinery during the present year. While, however, we have suffered like the rest of the trade from a diminution in the volume of business, I feel confident that we have not suffered more proportionately than our competitors, and, judging from our balance-sheet as compared with theirs, I should say we have suffered less. It is a pleasure to be able to assure you that the work we turn out gives complete satisfaction to our customers, many of whom come to us over and over again, because they know that our work is absolutely reliable. We send machinery to all parts of the world, and have orders from Government Departments under the most severe specifications and tests that can be devised. We do not shrink from these, for we can hold our own against any other manufacturer, both in excellence of design and perfection of work. You will readily realise that any diminution in orders is at once reflected in the manufacturing profit, because, as I have told you more than once, we cannot look for any further reduction of importance in our standing charges. These continue, however, to receive the closest attention, and a moderate saving was effected during the past year. While sympathising very fully with the ordinary shareholders in the absence of a dividend (and those of us on this side of the table are among the greatest sufferers), I must congratulate them upon the strong financial position of the Company, and I think you will recognise that to have strengthened our position as we have done during such troublous times proves the wisdom of the policy pursued by the Board. We have now no loans of any kind, our realisable assets are many times greater than our current liabilities, and we are in a position to pay prompt cash for all that we buy, and so command the best prices and discounts which prevail. Moreover, we have been able to redeem on favourable terms £40,000 of our second mortgage debenture stock, and an annual sum of £1,800, hitherto paid as interest,

Digitized by Google

will become available for dividends. The stock will be kept alive for the purpose of re-issue, if required, but the board do not at present foresee any necessity for this. Out of the surplus arising from the redemption we have placed £10,000 to the credit of general reserve fund, and we have a further substantial amount at the credit of a suspense account. In 1908 an action was brought against the company by a German firm for alleged infringement of a patent. The board obtained the advice of one or two leading experts, and were advised that there was no subject matter for a patent in the plaintiffs' specification. Being desirous, however, of avoiding litigation, the board entered into negotiations with the plaintiffs for a licence, but as reasonable terms could not be obtained the action was allowed to proceed. After extraordinary delay on the part of the plaintiffs, the case came before Mr. Justice Parker at the end of January of this year, and judgment, with costs, was given in favour of this company on all the issues. An appeal, however, has been lodged by the plaintiffs, which it is expected will be heard towards the end of this month. Pending the conclusion of this litigation, the board have, as I have already said, credited a sum to a suspense account. The items in the profit and loss account being all strictly comparable with those of last year, it is not necessray for me to go through them in detail. I may draw your attention, however, to a saving in debenture interest of £825 (which, as I have told you, will be increased to £1,800 this year) and also to a reduction of £597 in general charges. I now move the adoption of the report and accounts.

The MANAGING DIRECTOR (Mr. James Gray) briefly seconded the resolution, which was carried unanimously.

The retiring directors (Sir James Pender, Bart., and Mr. Philip Edward Beacheroft) and the retiring auditors were then re elected, and the proceedings terminated.

Chili Telephone Co. (Ltd.)

The twenty-first ordinary general meeting was held yesterday (Thursday) under the presidency of Mr. GEORGE KEITH.

The SECRETARY (Mr. Edmund Petley) having read the notice convening the meeting and the auditor's report,

The CHAIRMAN said: The report shows that our business in Chili has continued its general progress during the past year. The improvement shown has been due principally to the general commercial activity in the large centres of Santiago and Valparaiso, where the bulk of our business lies, and in a lesser degree to the year's good harvest and the general prosperity in the Central and Southern agricultural districts, while in the districts of Iquique and Serena little or no progress has been made in consequence of the depressed state of the nitrate and mining industries. The value of the currency, in which our revenue is collected, remained throughout the year low and practically steady at an average rate of exchange of 10½d. As a result the currency revenue in Chili shows an increase for the year of 8 per cent., while the working expenditure comes out at 70 per cent. of the revenue or 2 per cent. more than it did last year. The increase in the rate of working expenses was due to the higher price of materials and to the advancing cost of living, which involved an increase in salaries and wages. The income in Chili, when converted into sterling, shows an increase for the year of £2,713, and interest on investments and the year's cash balances is £453 more. Taking transfer fees into account, the gross income amounts to £41,685, or £3,171 more than last year. The total charge against income amounts to £3,415, or an increase of £228. The balance profit was £38,270, which, after providing the interim dividend of 3 per cent. paid in January and £20,504 for the reserve, enables the Board to recommend the payment of the usual final dividend of 5 per cent., making with the interim payment a total distribution for the year of 8 per cent., free of income tax, the same as last year, and to increase the balance carried forward by £166 to £2,987. After providing £737 for difference of exchange and £2,766 for replacements of plant, the reserve account shows an increase of £17,000, as against which £7,179 has been expended on new additions to the property and carried to the capital expenditure account. The stock account shows an increase of £4,286, due principally to the requirements of the underground work in course of construction, and investments are £5,956 more, bringing up the total cash reserve invested in outside securities to £35,774. As regards their property in Chili, besides the ordinary extensions, due to joining up new subscribers, 19 new offices have been opened during the year in the small towns of the Central and Southern districts. The trunk lines have also been increased and extended to meet the growing requirements for inter-town communication. The work of placing the wires underground in Santiago has been very much advanced during the year. Some of the cables have been laid and the subscribers' lines transferred to them, which is gradually relieving the congestion of overhead wires in the centre of the city. They were considering the advisability of capitalising a part of the reserve which has been invested in the business and of distributing it to the shareholders as fully paid-up shares, in order to put the issued capital of the Company more on a par with the value of the property. I now move the adoption of the report and accounts.

Mr. FRANK W. JONES seconded the motion, which, after a brief discussion, was carried, several shareholders congratulating the board upon the strong position of the Company, the proposal of the directors to divide a portion of the reserve amongst the shareholders being warmly approved.

A resolution approving the final dividend of 5s. per share was then carried unanimously, and, the retiring director and auditors having been re-elected, a hearty vote of thanks to the chairman and directors, proposed by Sir Alexander Henderson, brought the proceedings to a close.

CHILIAN ELECTRIC TRAMWAY & LIGHT CO. (LTD.)—At the meeting last week (Mr. L. Breitmeyer said the company's operations in Santiago during the past year showed a substantial improvement compared with 1908. The tramways had carried 7,000,000 more passengers and the receipts had improved by £54,000. The lighting and power department showed an increased profit of £34,000. They had placed £32,000 to reserve after paying the dividend on the 5 per cent. preference stock.

CITY & SOUTH LONDON RAILWAY CO.—The directors' report for half-year ended June 30, states that the receipts amounted to £88,832. 7s. 2d., and the cost of working was £42,212. 13s. 11d., leaving £46,619. 13s. 3d. profit. Inclusive of balance brought forward, net revenue account shows an aggregate of £47,331. 19s. 4d. After making provision for debenture stock interest, rent charge, and transfering £1,500 to renewal fund, a balance remains of £31,185. 12s. 5d., out of which the directors recommend the full dividend of 5 per cent. per annum on the preference stocks, and a dividend at the rate of 1¼ per cent. per annum upon the consolidated ordinary stock for the half-year, leaving £1,634. 9s. 5d. to be carried forward. The number of passengers (exclusive of season ticket holders) carried was 11,497,140 (compared with 11,227,179 in the corresponding half of 1909. The increasing competition of the tramways remains unabated, and the electrifying of the Brighton Co.'s line from London Bridge to Victoria has not tended to increase the City & South London Co.'s receipts between London Bridge and Clapham. The admissions to the Anglo-Japanese Exhibition at Shepherd's Bush have been adversely affected by current events, and the interchange traffic between the tubes and other railways has consequently fallen below expectations. The directors regret, therefore, that owing to these causes, to increases in wages bill and in coal and other stores, and to some exceptional repairs, they have no alternative but to recommend a diminished rate of dividend on the ordinary stock. The erection of the emergency staircase at the Brighton Co.'s end of the subway at London Bridge is completed. The Bill promoted by the Metropolitan Railway Co. to authorise the construction of a low level subway at Moorgate-street to connect the stations of the Metropolitan, G.N. and City and City & South London Railways has passed through committee in both Houses of Parliament. The contract for the construction of the high level subway between the Bank station of the Company and that of the Central London has been placed, and the work will proceed without delay.

GENERAL ELECTRIC CO. (LTD.)—For the year ended March 31 the net trading profits and income from investments, &c., were £95,461. 12s. 6d.; deducting depreciation and debenture interest (£27,057. 8s. 10d.) the balance was £68,404. 3s. 8d. Preference dividend absorbed £12,500, leaving £55,904. 3s. 8d. The directors recommend that this be appropriated as follows: Provision for managing directors' and employés' bonus £5,590. 8s. 4d., dividend on ordinary shares of 5 per cent. for the year £19,395, reserve £22,000, leaving £8,918. 15s. 4d. to be carried forward. This brings the reserve to £158,488. The result of the trading for the year has been satisfactory, and the factories at Witton, Salford, Birmingham and London have been well employed. The switchgear arc lamp and small motor departments have been removed from Salford to Witton. Peel Works, Salford, are now entirely devoted to the manufacture of telephone and telegraph apparatus. The directors have thought it desirable to carry on these departments as a subsidiary company, and part of the assets of these works now appears under investments.

GRINDELL-MATTHEWS WIRELESS TELEPHONE SYND. (LTD.)—At the statutory meeting on Wednesday, Sir J. Clifton Robinson said, having regard to the exceptional character of the undertaking, and with a view to conserving the interests of the shareholders, it had not been deemed desirable to issue more shares than were necessary for providing funds for their immediate requirements. Negotiations were in progress for the sale of certain foreign rights of the syndicate. Representatives of several public bodies had come over from the Continent, to have the telephone explained to them, and he had been informed that their experts had expressed themselves satisfied with the demonstration. The board proposed to make it a condition of the acquisition of any of the company's foreign rights that the purchaser should subscribe for a holding in the present syndicate, thus maintaining an interest in it. They had just completed their works on the Bristol Channel.

MADRAS ELECTRIC SUPPLY CORPN. (LTD.)—In the report for 1909 the board express regret at the death of Sir Ralph D. R. Moor, one of the directors. The construction contract is now practically completed, although the plant has not yet been officially taken over from the contractors. Tramway supply commenced on Jan. 12 last. The board have placed the whole of the working costs up to Dec. 31 last (less receipts) to a suspense account, which will be written off by instalments out of future profits. On April 3, when the supply from the permanent plant commenced, the equivalent of 5,200 8 c.p. lamps was connected to the mains, and at Dec. 31 the equivalent number was 29,057, with 4,562 more awaiting connection, and at the date of the last report (June 16) the number had increased to 40,981, with 5,105 awaiting connection. The tramway demand is equivalent to 16,666 lamps. The licences applied for by the company to enable a supply of electricity to be made to the Port Trust at Madras and to Fort St. George have been granted, and supply has commenced. Applications are frequently being received for extensions of mains for supply of current to new consumers. In order to meet the outlays required for such extensions, to pay off the loan from the bankers and to provide an adequate working capital, the directors propose to make an issue of £100,000 of 6 per cent. first mortgage debentures, which will shortly be offered to the shareholders.

UNITED RIVER PLATE TELEPHONE CO. (LTD.)—The directors' report for the year ended March 31 states that the gross receipts in the River

Digitized by Google

Plate were £336,422. 4s. 3d., against £287,064. 11s. 8d. for 1908-9. Deducting expenses in Argentina and London, debenture interest, preference dividend and interim ordinary dividend, and adding interest, &c., there remains £95,557. 18s. 3d., added to £5,138. 1s. 5d. brought forward, making £100,695. 19s. 8d. After making the proposed appropriations, the directors recommend a final ordinary dividend of 5 per cent., making 8 per cent. for the year (tax free), and that the balance of £4,633. 9s. 8d. be carried forward. The steady and satisfactory increase of the business necessitates the introduction of further capital, and it is therefore proposed forthwith to make a fresh issue of 40,000 ordinary shares to the ordinary shareholders at par. For this purpose an increase in the nominal capital will be required, and a resolution to that effect will be submitted at the forthcoming meeting.

NEW COMPANIES, MORTGAGES AND CHARGES.

NEW COMPANIES.

G. W. CLARKE & CO. (LIVERPOOL) (LTD.) (110,604)—Reg. July 5 capital £1,000 in £1 shares (250 deferred), to take over as a going concern the branch business of electrical engineers carried on by the Walsall Electrical Co. in Liverpool, to acquire from G. W. Clarke the benefit of certain licences and inventions relating to appliances and devices for indicating and recording temperature and otherwise. Private company. First directors, E. B. Barron (chairman) and G. W. Clarke.

CONTRAFLO CONDENSER & KINETIC AIR PUMP CO. (LTD.)—Reg. June 18, capital £80,000 in £1 shares, to carry on the business of inventors, dealers in patents, engineers, founders, mechanicians, &c., to acquire invention relating to the manufacture, production, treatment, application and use of boilers, engines, condensing, pumping and cooling plant, &c., and to adopt certain agreements, &c. First directors D. B. Morrison and C. W. Milne. Reg. office, 3 and 5, Crown Court, Old Broad-street, London, E.C.

DRILLS (LTD.) (110,603)—Reg. July 5, capital 2,000 in £1 shares, to carry on the business of engineers, founders, manufacturers and patentees of electric and other drills, and to adopt an agreement between R. S. Crawford and J. Scott for the acquisition of electric mining drill and other electrically driven percussive tools, instruments, &c., and patents in respect thereof. Private company. First directors, R. S. Crawford and J. Scott (provisional).

ELECTRIC FURNACES & SMELTERS (LTD.) (110,576)—Reg. July 4, capital £5,000 in £1 shares, to carry on the business of smelters, refiners, treaters and amalgamators of ores and other metalliferous and mineral substances, manufacturers of electrical or other furnaces for smelting, &c. Private company. Reg. office, 110, Cannon-street, London, E.C.

ENGINEERS' STANDARDISED PUBLICATIONS ASSOCIATION (LTD.) (110,652)—Reg. July 7, capital £2,000 in £1 shares, to take over the business of agents for the classification and distribution of manufacturers' trade circulars and price lists of engineering requisites carried on by F. Samuel and J. D. B. Innes as the Engineers' Standardised Publications Association. Private company. First directors, F. Samuel, J. D. B. Innes and J. C. Butler.

HIGH-SPEED PRINTING TELEGRAPH CO. (LTD.) (110,630)—Reg. July 6, capital £2,000 in £1 shares, to carry on the business indicated by the title. Private company. R. Warner, of 10, Walbrook, London, E.C., is the first secretary.

NOKES & CANNON (LTD.) (110,444.)—Reg. June 28, capital £2,000 in £1 shares, to carry on the business of engineers, founders, smiths, machinists, &c., and to adopt an agreement with E. S. Nokes and J. J. Cannon for the acquisition of the business of mechanical and electrical engineers formerly carried on by E. S. Nokes at Leicester as Clerk & Nokes. Private company. First directors, E. S. Nokes and J. J. Cannon. Reg. office, Canning-street, Leicester.

PHŒNIX ILLUMINATED ADVERTISING SYND. (LTD.) (110,420.)—Reg. June 27, capital £2,000 in £1 shares, to carry on the business of advertisers, advertising agents, manufacturers of advertising appliances, suppliers of electricity, &c. Private company.

THOMAS BRITTAN (LTD.) (110,549.)—Reg. July 1, capital £500 in £1 shares, to take over the business of telegraph, telephone and electrical instrument manufacturers and telegraph engineers carried on by W. T. Brittan and T. E. Want as Thomas Brittan. Private company. First directors, W. T. Brittan, T. E. Want and E. W. Cairns. Reg. office, 34, Risinghill-street, Pentonville, London, N.

WITTON, JAMES (LTD.)—(110,693)—Reg. July 8, capital £6,000 in £1 shares (2,000 preference), to carry on the business of manufacturers of and dealers in electrical driving equipments for printing, textile and paper-making machinery, electric blowers, flexible couplings, &c., and to adopt agreements with the General Electric Co. and H. V. James. Private company. First directors, H. V. James, A. H. Railing and A. I. S. Baron. Reg. office, 71, Queen Victoria-street, London, E.C.

STATUTORY RETURNS.

CHISLEHURST ELECTRIC SUPPLY CO. (LTD.)—In return to May 2 capital is £15,000 in £5 shares. All shares taken up and paid for in full. Mortgages and charges, £10,000.

DOWSING RADIANT HEAT CO. (LTD.)—According to return dated Nov. 5 capital is £12,000 in £1 shares. All shares taken up. £1 per share called up on 6,970, 5s. per share on 5, and nil on 25. £6,971. 5s. paid. 5,000 shares considered as fully paid. Mortgages and charges, £9,971 debenture stock.

ELECTRIC SIGN & GENERAL ADVERTISING CO. (LTD.)—Return to March 30 gives capital as £5,000 in £1 shares. 2,000 shares taken up. £1,000 paid. £1,000 considered as paid. Mortgages and charges, nil.

GUILDFORD ELECTRICITY SUPPLY CO. (LTD.)—According to return to April 13 capital is £55,000 in 25,000 preference shares of £1 each and 6,000 ordinary shares of £5 each. 15,976 preference and 2,802 ordinary shares taken up. £29,988 paid, including £2 on two ordinary shares forfeited. Mortgages and charges, £25,000. (165 preference shares have been allotted for cash since date of above return.)

METROPOLITAN ELECTRIC SUPPLY CO. (LTD.)—In return to March 22 capital is £1,500,000 in 200,000 ordinary and 100,000 preference shares of £5 each. 200,000 ordinary and 76,121 preference shares taken up. £5 per share called up on 195,936 ordinary and 76,121 preference. £1,360,285 paid. Mortgages and charges, £483,000.

A. REYROLLE & CO. (LTD.)—Return to April 5 gives capital as £40,000 in £1 shares (20,000 preference). 17,500 ordinary and 19,019 preference shares taken up. £1 per share called up on 10,500 ordinary and 19,019 preference. £29,519 paid. £7,000 considered as paid on 7,000 ordinary. Mortgages and charges, £14,400.

MORTGAGES AND CHARGES.

MORRIS & LISTER (LTD.)—Particulars of £3,000 debentures, created by resolutions of June 2 and 21, 1910, filed pursuant to sec. 93 (3) of Companies (Consolidation) Act, 1908, whole amount being now issued. Property charged, company's undertaking and property, including uncalled capital. No trustees.

SUNBEAM LAMP CO. (LTD.)—Issue on June 30 of £6,250 debentures, part of a series of which particulars have already been filed.

TELEGRAPH & TELEPHONE INSTRUMENTS (LTD.)—Particulars of £600 debentures, created June 20, have been filed; amount of present issue £500. Property charged, company's undertaking and property, present and future, including uncalled capital. No trustees.

RECEIVERSHIP.

MAXIM ELECTRICAL CO. (LTD.)—Notice of appointment of H. J. Morland, of 3, Frederick's-place, Old Jewry, E.C., as receiver, on June 4, under powers contained in indentures dated March 9, April 2 and Oct. 29, 1908, has been filed.

CITY NOTES.

MEMORANDA (July 14).—Bank rate 3 per cent. (since June 9, 1910). Price of silver, 25d. per oz. Consols 81⅛—82⅛ for money; 82—82⅛ for account. Consols Pay Day, Aug. 4; Stock and Shares Continuation Days, July 26 and Aug. 10; Ticket Days, July 27 and Aug. 11; Pay Days, July 28 and Aug. 12; Mining Shares Carry Over Day, July 25.

PRICES OF METALS (London).—*Copper*, cash, 53¾; three months, 54. *Lead*, English, 12⅞—13⅛; foreign, 12⅜. *Spelter*, 22⅜. *Tin*, English, 147—149; foreign cash, 148⅜; three months, 149⅞. *Iron*, Cleveland, cash, 48/9½, three months, 49/7.

BOURNEMOUTH & POOLE ELECTRICITY SUPPLY CO. (LTD.)—The directors have declared the usual interim dividends upon the 4½ per cent. preference and the 6 per cent. second preference shares (less tax) for the half-year to June 30, and also an interim dividend on the ordinary shares at the rate of 5 per cent. per annum (less tax) for the same period.

CITY OF LONDON ELECTRIC LIGHTING CO. (LTD.)—The directors have declared an interim dividend on the ordinary shares of 6s. per share, less tax.

DIRECT UNITED STATES CABLE CO. (LTD.)—The Board has resolved to recommend a final dividend of 4s. per share, together with a bonus of 2s. per share (both tax free), such dividend and bonus to be payable on and after the 30th inst., and making, with the three interim dividends already paid, a total distribution of 4½ per cent. for the year ended June 30, after placing £5,000 to reserve and carrying forward about £4,783. The transfer books will be closed from the 12th to the 26th inst. inclusive.

PARA ELECTRIC RAILWAYS & LIGHTING CO. (LTD.)—The directors announce a dividend on the ordinary shares at the rate of 8 per cent. for the half-year ended May 31. The reconstruction of the old mule tramways and certain improvements to the lighting system were completed in 1908 by the contractors, Messrs. J. G. White & Co., of London, and in 1909 the company purchased a majority of the shares in the other electric supply company in Para. The gross receipts for 1909 were £225,917 (against £205,311 in 1908); the operating expenses £120,310 (against £152,637); and the surplus was £60,590 (against £16,214). The first half of the current year shows cabled net earnings of £62,360, representing an increase over a similar period in 1909 of £18,253.

STOCK EXCHANGE NOTICES.—The Stock Exchange committee have appointed July 27 a special settling day in, and have granted a quotation to 30,000 £1 fully paid vendors' preferred ordinary and 90,000 £1 fully paid vendors' deferred ordinary shares of the *National Telewriter Co. (Ltd.)* The committee have also ordered £1,000,000 4½ per cent. first and general mortgage 30-year bonds (issued in Amsterdam) of the *New York Telephone Co.*

TELEGRAPH CONSTRUCTION & MAINTENANCE CO. (LTD.)—The transfer books will be closed from 11th to 19th inst., inclusive, preparatory to payment of an interim dividend of 12s. per share.

NOTES.

A Clearing House for Goods in London.

WE do not doubt that the man in the street, when he receives a parcel, or a box of goods, has but the faintest idea of the amount of labour that has generally been spent upon directing that parcel, or box, to its destination. It is only necessary to look at a map of London on which the goods stations and goods depots of one kind and another are marked to realise what a large area is taken up in the process of sorting. This large area postulates a very inefficient process. A small sorting establishment is easy in its manipulation, but the larger the depot the greater the difficulty in this direction. The chief trouble is that the difficulty of working does not increase merely in the same proportion as the number of parcels handled, but increases in a considerably greater ratio, just like the handling of calls in a telephone exchange. Consequently any difficulty which now exists will not be diminished, if our present system be maintained, but will be much intensified as time goes on. So far the method adopted seems to be the most primitive, consisting simply of manual sorting, and no amelioration can be expected so long as this method is retained.

IN another column we give an account of the solution proposed by Messrs. A. W. GATTIE and A. G. SEAMAN. The broad principle of belt conveyors is quite familiar, but such a principle does not go far enough. It is almost necessary that the belt conveyors should be endowed with some form of discrimination if an effective system is to be evolved. The ingenious devices of Messrs. GATTIE and SEAMAN appear to meet the need in this respect, so that it becomes only necessary to set a form of controller where the parcel is dispatched, and the parcel will then travel to the required point on the sorting floor, where all parcels for the same destination would thus be collected. An examination of the scheme shows that what is required is quite feasible in principle, and we therefore hope that a serious attempt will be made to prove its claims in practice. Mr. GATTIE is ambitious in coming forward with the suggestion to have a huge clearing house for goods for the whole of London. Such a scheme is magnificent in conception, but we may, perhaps, be pardoned for saying that we should like to see something on a smaller scale first. Everyone who has had experience in engineering matters knows that difficulties are almost certain to arise in the operation of entirely new plant. These difficulties may be merely matters of detail, but nevertheless they give trouble, and it is more easy to eliminate them on a small scale than on a large one. We would therefore suggest that in the first instance Messrs. GATTIE and SEAMAN should make a large size model to demonstrate the working of the system, after which we hope that financial support will be sufficient to enable a clearing house to be erected in one of the provincial towns where most valuable experience would be gained in proving the feasibility of the London scheme proposed by Mr. GATTIE.

Electrical Progress in St. Marylebone.

WE are glad to see by the report and accounts issued last week that the Marylebone undertaking has now turned the corner and is making a substantial profit after meeting all capital charges. A year ago a modest estimate was made that the year just closed would show a net profit of £1,341, but the actual result has been a net profit of £8,482, compared with the debit balance of £3,930 which was the result of the previous year's working. This result must be very gratifying to all concerned. The improved position is, no doubt, due to many causes, and among the economies which are most noticeable we may mention that although there was an increased output of 1,775,598

Digitized by Google

units, or 19·7 per cent., yet the total expenditure was £1,368 less than in the previous year. The costs per unit sold have now fallen below 1d., being actualiy 0·961d. In the report reference is made to the bonus scheme in operation at the works as being a fruitful source of economy on the generation account. We have no details of the particular scheme employed, but we do not doubt that much can be done by making economies personally advantageous. Moreover what is true of the stoker and driver is true in a more limited sense of the superior officers; and doubtless for this reason the Electricity Committee have recommended, provided the output increases by at least 500,000 units per annum and the cost per unit diminishes by 5 per cent., that 6 per cent. of the first £10,000 of the profits and 9 per cent. on anything beyond this sum should be distri buted among the chief officers. Since the success of an undertaking of this kind is so essentially dependent on the efforts of the responsible officers, it is only fair that when good progress is made the staff should benefit, and few of us are free from the very human feeling that reward is an incentive.

We need scarcely remind our readers that the Marylebone undertaking is severely handicapped by heavy capital charges; in fact, this item in the total costs amounts to 1·42d. per unit sold, so that it is something of an achievement to have reduced the selling price to an average of 3·66d. Moreover, the load factor is distinctly poor, being 15·7 per cent., though this is a considerable advance on 13·6 per cent., which was the figure in 1907-8. Reference is made in the report to the sales department, which has been the object of considerable criticism at times. We are glad to see it stated that the policy of the Council is not to take work out of the hands of private contractors, and that in some cases the Council's staff has been withdrawn as soon as it has been found that a contractor was already dealing effectively with the work in hand. It is also stated that a fair profit has been obtained on the work carried out, and that no attempt is made to compete unfairly with private enterprise. In regard to hire and hire-purchase, not very much has been done up to the present, but the progress that is being made is stated to be satisfactory. Certainly, whatever opinions may be held in regard to wiring by municipalities, there can be very little question as to the importance of carrying on a business of hiring out plant if electricity supply is to meet effectively the very keen competition by gas. Mr. Seabrook has some hard work before him, but we do not doubt that now the undertaking has turned the corner the progress in successive years will be very rapid.

Tramway Development in London.

Ten years ago London was justly the laughing-stock of many provincial towns, for it was only just then begining to possess electrically-driven tramways, and, in certain districts, still relied mainly upon obsolete horse-worked cars for travelling from place to place. The reasons for this regrettable state of things were many and complicated. There existed persons who thought the old methods were good enough; there were also those who wished to see the new system introduced, but who wished to make as much as possible out of the change; while a third class opposed for the sake of opposing. Restrictive legislation, too, was a large factor in the case, for no company could be expected to spend money on drastic changes when the life of their undertaking had but a few years to run. Owing to more favourable conditions, the London United Tramways Co. just ten years ago opened an electrically-worked section from Hammersmith and Shepherd's Bush to Acton, using the same route over which the old horse tram company had worked. By degrees, with great expenditure of capital and in spite of regrettable tac'ics by the local authorities concerned, the same company gradually extended their borders along the principal trunk roads in west and south-west London, and even out into the surrounding country. Some years after, the Metropolitan Electric Tramways Co., in conjunction with the Middlesex County Council, laid down several miles of line in the northern suburbs, also extending outside the county boundaries into the neighbouring districts. The authority, however, which has done most towards helping the development of electric traction in London is undoubtedly the London County Council. After acquiring the rights of the existing horse tramway companies both in south and north London, this authority opened their first electrically-worked section in 1904. Though we have from time to time found it necessary to criticise certain actions of the Council, both financial and engineering, with regard to their tramway system, we have never had anything but praise for the general way in which they have carried out their policy in spite of opposition, not only emanating from interested local authorities (chiefly from the borough councils as the road authorities) but from within the Council itself.

At the meeting of the Council on Tuesday last it was proposed to constuct another 22½ miles of track. The completion and setting to work of these extensions will practically complete a network of lines extending over almost the whole of outer London and even into the suburbs and country districts beyond, not wholly owned by the Council but working in connection with their system. There are now 113½ miles of electrically worked lines in operation, as well as 19 miles on which horses are still used. The total weekly income from the whole system is £56,700. The number of cars employed is 1,200, while 250 more are in course of construction. The number of passengers carried during the past 12 months was 451,000,000, practically 150,000,000 more than were carried three years ago. The system is, in fact, still spreading, though not at so rapid a rate as was once the case, and when it is complete there will be at least 150 miles of electric tramways in operation within the county, capable of carrying about 15,000,000 passengers per week.

London may be behindhand in taking up new things, but not the most convinced provincial can now say that she is backward in tramway matters. The problems that have to be faced are not the same as those met with in Liverpool or in Manchester. Unless extensive rebuilding is to take place many London streets will always be quite unsuitable for tramway working, while, in others, for many reasons, cars could not be admitted. To have a line laid down either in Fleet-street or Piccadilly would

Digitized by Google

be unthinkable. Nevertheless, there has been plenty of room for development in outer areas, and it cannot be denied that the County Council has seized its opportunity in these districts. On certain details of policy it has perhaps laid itself open to criticism, but in spite of this it has provided London with a tramway system of which we may well be proud.

Personal.—We understand that Mr. J. H. Rider is resigning his position as chief electrical engineer to the London County Council, and is joining Messrs. H. Eckstein & Co., at Johannesburg, in September, his position being an advisory one in regard to the large amount of engineering plant in use by the company. Mr. Rider's many friends will congratulate him on his new appointment, but will be sincerely sorry that his work should be so far removed from the metropolis.

The Late Mr. Harry W. Cox.—It will be seen that a proposal is made in our correspondence columns that a fund should be provided for further assisting the wife and family of Mr. H. W. Cox, the X-Ray enthusiast, whose lamented death was recorded in our last issue. A question was asked in Parliament on Monday as to whether Mrs. Cox would be recommended for a Civil List Pension. The Prime Minister said it was impossible to make any statement at the present time, but he would consider any representations that were made to him.

Sir Wm. Crookes and the Order of Merit.—An announcement in "The Times" states that Sir William Crookes wishes to thank his numerous friends who have congratulated him on receiving the Order of Merit. He hopes they will excuse his delay in replying personally to each, as their gratifying letters have arrived in such overwhelming numbers that many weeks must elapse before he will be able to clear up arrears of correspondence.

Wireless Telegraph Developments.—The isolation of the Austrian Lloyd liner "Trieste," consequent upon that vessel not being equipped with wireless telegraph apparatus, has called particular attention to the necessity for all vessels carrying passengers being provided with facilities for wireless intercommunication with ships at sea and with stations on shore. All the principal legislatures of the world are considering the subject of the compulsory equipment of passenger vessels, and these proceedings tend to show that the system is making a great advance. Amongst the manufacturing companies which will benefit by this general demand will be the parent company over which Mr. Marconi presides, and the manufacturing side of that undertaking should take a very prominent place in this development. Recently published statements show that a number of important equipments have been placed in the company's hands for execution. Already most of the important steamship lines have adopted wireless, and of these a large proportion are equipped with Marconi apparatus having a range of from 100 to 300 nautical miles. The effect upon marine insurance rates is so considerable as to prove a great inducement to steamship owners to adopt this modern and extremely useful means of intercommunication. There is full evidence that these installations will serve the purpose we have always contended they would serve, that of feeding the submarine cable and land line services of the world, and from this point of view a wider interest even than that of the development of wireless telegraphy is concerned. In other directions the development of wireless telegraphy is proceeding. There have been a number of instances recorded of wireless telegraphic communication being successfully carried on between stations erected on the surface and temporarily erected stations in mines and other underground situations. We recorded a case only the other day at the Chislehurst caves, and now we read in the Berlin "Tageblatt" of some interesting experiments made by Dr. Löwy and Dr. Leimbach in the potash mines at Dienenburg. These investigators made a series of trials and succeeded with very simple apparatus in exchanging signals at long distances and through several levels of the mines. These signals proved so satisfactory that it is thought much greater depths can be dealt with and that this branch of wireless telegraphic development is a very promising one. It should provide another source of revenue to manufacturers of all systems of wireless operation.

New London-Paris Telephone Cable.—Some interesting preliminary experiments were made on this new telephone cable last week by a party of engineers, at the invitation of Major W. A. J. O'Meara, Engineer-in-Chief of the Post Office. It will be remembered that the cable was recently laid from Dover to Cape Grisnez, and as the use of Pupin coils was really an experiment (no cable so long as this having yet been laid on this principle), the new cable was in general construction made of precisely the same type as the old cable, viz., each core, per naut, consisted of 160 lb. of copper and 300 lb. of gutta percha; so that if the new cable proved a failure owing to the breaking down of the loading coils, it would be a simple matter to cut out these coils, which are spaced 1 naut apart, and thus obtain a cable as good as the old one, the cutting out of the coils costing a few hundred pounds only. The coils each have an inductance of a little over 100 millihenries. The object of the experiments was to compare the old and the new cables. With this object the cables were looped at the French end (Cape Grisnez) and observations made at the English end (Abbotts Cliff) by speaking through the looped cable, the speaker being in one room and the listener in another room, lengths of "standard cable" being added on until the limit was reached at which speech became uncommercial. The following results were obtained :—

Observer.	Old Cable. Added length of standard cable.	New Cable. Added length of standard cable.	Gain by new cable.
W. Judd	26 miles symmetrical	40 miles symmetrical	14
J. E. Kingsbury	26 „ „	40 „ „	14
W. Duddell	24 „ „	40 „ „	16
		*50 „ „	...
		*55 miles at one end	...
W. R. Cooper	24 „ „	48 „ symmetrical	24

* As breakdown limit of hearing.

By "symmetrical" is meant that the "standard cable" length was split up, half being connected to each end of the telephone cable. It will be seen that the mean gain by the new cable was 17 miles of standard cable. Taking a mean figure, 21 miles of standard cable was the length that could be spoken through when joined up at each end. This means that conversation can be carried on at a place over 450 miles distant from Dover in England to a place equally distant from Calais on the French side, if aerial land-lines are used weighing 800 lb. to the mile, such as are in use between Glasgow and London. The following are details of typical trunk circuits from London to some of the more important provincial towns.

Typical trunk circuit.	Standard cable equivalents. Existing, which include several short underground sections.	Standard cable equivalents. If sections of underground cable were replaced by open wires.	Loss due to requirements of local authorities in regard to underground.
London-Liverpool	12·5	7·077	5·423
London-Newcastle	14·97	10·95	4·02
London-Dublin	28·01	*26·128	1·882
London-Glasgow	15·5	13·158	2·342

* Includes 13·7 standard cable miles for submarine cable.

Some of the observers noticed a very marked improvement, as regards clearness of speech, in the new cable over the old cable when the cable alone was in circuit.

Starting Device for a Squirrel-cage Rotor.—According to the "Electrical World," it is proposed in a patent issued to Mr. S. R. Bergman to improve the starting torque of a squirrel-cage induction motor by providing two end-rings in parallel, one of low and the other of relatively high resistance. A laminated iron ring mounted on the rotor shaft is so arranged that it can be shifted to or from the low-resistance end-ring and in this way vary the reactance of this circuit. When starting, the reactance of the low-resistance circuit is a maximum, and more current will be carried by the high-resistance ring than by the low-resistance ring, thus reducing the total current and increasing the torque.

Railway Engineers on Electric Traction.—At the International Railway Congress which concluded its sittings at Berne last Saturday the modern development of railway operation received attention in four reports. Mr. George Gibbs, the reporter for America, dealt with electric traction on existing steam railroads. He said that all first costs of conversion of steam roads to electric working must be dealt with separately, experience being in such cases no guide. He presented tables showing that the Long Island line operated its electric sections at a cost of 9d. per car-mile, against steam traction costs of 1s. 2d. An interesting report brought up by Dr. Gleichmann dealt with the preliminary work necessary before the introduction of electric operation on German main railway lines. The reporter stated that when it was a question of introducing electric traction on large connected systems an alternating system would be preferred. The Swiss Federal railways, it was stated, were also contemplating the adoption of electric traction on their international lines. The Austrian State railways were reported to have the subject of main line electrification under consideration, the proposal being to convert 2,690 miles of line, within range of available water powers, on the single-phase system. The discussion on these reports seemed to indicate that at no distant date long lengths of Continental main lines would be converted to electric work, and the single-phase system would be generally employed, the power being generated by hydro-electric plants. In Great Britain, with cheap coal and but little available water power, the subject of main line electrification was not likely to receive serious consideration at present. It would involve, in the opinion of the speakers, an enormous capital expenditure without any adequate return. For the operation of traffic in dense centres of population the advantages of electrical working were apparent enough, but main line traffic was on an entirely different basis.

Current Topics.

Subjects of current interest dealt with in this issue include the following:—

Mr. J. Rezelman contributes an article on "Analysis of Leakage Reactance."

Last week a meeting of consulting engineers was held, when the desirability of forming an association for the protection of the interests of consulting engineers was considered, and it was definitely decided to form such an association. A strong committee, consisting of civil, electrical and gas engineers was elected to carry the scheme to completion.

We give an account of the system which Messrs. A. W. Gattie and A. G. Seaman propose to employ for the mechanical sorting of parcels and goods, the object being to centralise such operations and to reduce them to the simplest possible character.

At the meeting of London County Council last week the Finance Committee submitted an interesting report on the life of electric generating plant and the periods to be allowed for repayment of loans.

The Council have been recommended by the Highways Committee to obtain sanction for the construction of 10 additional tramway routes, equal to about 22 miles of single line, at an estimated cost of £462,470.

Hampstead (London) Council have authorised the conversion of 802 additional gas lamps to incandescent electric lighting.

Messrs. Mordey & Dawbarn have prepared a report on the Torquay tramways, in which they express the opinion that the present Dolter system could be improved so as to give satisfaction.

Hackney (London) Council have decided to extend their feeder and distributing cables at an estimated cost of £18,364. In order to encourage the use of electricity for cooking and heating and other domestic purposes, a revised scale of charging, somewhat similar to that in use in Marylebone, is to be adopted.

At a conference of representatives of the Urban District Councils of England and Wales a resolution calling attention to the present unsatisfactory state of the law with regard to the assessment of tramways was passed, and the Local Government Board was urged to introduce a bill providing for the assessment of all tramways or railways running through or along the public streets at a full net annual value.

An inquiry was held last week at Dundalk by the electrical adviser to the Board of Trade, Mr. A. P. Trotter, into the objections made to the electricity supply scheme of the Council.

Keen competition, the scarcity of contracts and the general depression in business has adversely affected the past year's financial result of Messrs. Crompton & Co. The directors, however, report that the outlook gives some sign of improvement, and economies that are being effected will, it is hoped, and anticipated, improve the general situation.

At a meeting of the Telegraph Construction and Maintenance Co. on Tuesday it was announced that Lord Selborne had accepted the position of chairman.

Legal.—Mr. Justice Neville last week commenced the hearing of an action brought by the Attorney-General (on the relation of the India Rubber, Gutta Percha & Telegraph Works Co.) against West Ham Corporation for a declaration that overdrafts obtained by the defendants from their bankers in respect of their electricity undertaking were illegal, and that the Corporation were not entitled to levy a rate for paying off the overdrafts or interest thereon, and an order was also asked for to compel the bank to refund the interest already paid in respect of the alleged illegal overdrafts. The hearing of the case was concluded on Tuesday, and judgment was reserved, but the bank agreed to refund £7,000, money paid to them as interest.

An important Factory Act suit was argued before the bench of magistrates at Houghton-le-Spring last week, the Newcastle-on-Tyne Electric Supply Co. being summoned for employing a person to carry out work at their electricity generating station who was not "competent" for such employment. The prosecution was undertaken by the Director of Public Prosecutions, and the case for both parties was skilfully argued by Mr. H. S. Mundahl and Mr. W. S. Burton.

Companies' Meetings and Reports.—The directors' reports of the Mexican Light & Power Co. and the Mexico Tramways Co. give particulars of the progress made with their hydro-electric transmission schemes during the past year.

INSTITUTIONS AND SOCIETIES

Lectures on Law Relating to Engineering.—The Council of the Junior Institution of Engineers, in conjunction with the Council of the Society of Engineers, have arranged for a course of six fortnightly lectures on "The Law Relating to Engineering," to be delivered by Mr. L. W. J. Costello, M.A., LL.B. (Cantab). The lecture will be given on October 10th next.

ARRANGEMENTS FOR THE WEEK.

INSTITUTION OF MECHANICAL ENGINEERS.

TUESDAY, July 26th.

10 a.m. Joint Meeting with the American Society of Mechanical Engineers at the Birmingham and Midland Institute. Reception by the Right Hon. Lord Mayor of Birmingham. The reception will be followed by the reading and discussion of Papers of mechanical interest.

WEDNESDAY, July 27th.

10 a.m. Meeting at the Birmingham and Midland Institute. Papers of mechanical interest will be read and discussed.

FRIDAY, July 29th.

10 a.m. Meeting at the Institution of Civil Engineers, Great George-street, London, S.W. Papers on "Electrification of Suburban Railways," by Mr. F. W. Carter; "Cost of Electrically Propelled Suburban Trains," by Mr. H. M. Hobart; "Economies of Railway Electrification," by Mr. W. B. Potter; "Electrification of Trunk Lines," by Mr. L. R. Pomeroy; and "Electrification of Railways," by Mr. G. Westinghouse.

CLEARING HOUSE FOR GOODS IN LONDON.

Summary.—An account is given of the means proposed by Messrs. A. W. Gattie and A. G. Seaman for the handling of goods and parcels mechanically. The means adopted consist essentially of two moving belts and an electric controller which ensures the goods being transferred from any one point to any other desired point. In conclusion, brief details are given of the "clearing house" which Mr. Gattie proposes for handling all the goods and parcels that require sorting in London to reach their destination.

In our issue of July 1 we gave a brief account of a lecture by Mr. A. W. Gattie before the London Chamber of Commerce, in which he advocated the establishment of a "clearing house," where all bales, crates and parcels would be sorted and whole loads shunted, the handling being effected almost wholly by mechanical means. There is no question that an enormous amount of delay occurs, and much labour is involved, in the primitive method that still holds, and must continue to hold, unless mechanical means are developed, for the sorting of parcels and goods and sending them on a fresh stage of their journey, inevitably for another sorting before their destination is reached.

Mr. Gattie pointed out that the present system of having large goods stations for the sorting of goods is an unsatisfactory way of carrying out this work on account of the very unwieldy nature of the goods stations themselves, this feature defeating their purpose as places of exchange. The primary object of a goods station is to provide a meeting place where vehicles can exchange their loads from rail to rail or road to rail, and *vice versa*, but at existing goods stations vehicles are frequently compelled to remain a good distance apart. Platforms are sometimes 1,200 ft. long, and, owing to lack of design, it is impossible for two vehicles, transferring a load from one to the other, to come near to each other, their average distance apart being 600 ft. Thus, there is a good deal of carting by means of hand trucks over quite considerable distances, and these have to be manipulated over areas which are very congested.

The result of having several separate goods stations is that many vans are to be found in the streets more or less empty, and it is a common thing for vans to wait a long time to pick up their loads, either at railway goods yards or at business premises, owing to the fact that the parcels must be submitted to sorting before they are delivered to the vans. A goods clearing house would avoid all this, because the sorting would be done at the clearing house instead of at many separate establishments. Consequently, if a van called for parcels at any premises these would be delivered to the van irrespective of destination, and much time would be saved. There would also be a corresponding improvement in the congested state of London traffic.

The adoption of such a system would bring benefits to the railway companies, for, apart from the freeing of valuable sites now occupied by goods stations and the saving of time and expense in handling goods, the rolling stock could be put to more efficient use. A great part of the time of goods rolling-stock at the present time is taken up in loading and unloading, and in the marshalling of trains, &c. Mr. Gattie states that according to an analysis of the Board of Trade figures the average mobility of a laden wagon is only 6 minutes in 24 hours, *i.e.*, it is on the move doing useful work for only 31 hours during the year. A lot of this wasted time could be saved if the goods trains could be run into a clearing house where the goods would be mechanically sorted to a large extent.

General Scheme.—At present we do not wish so much to deal with the obvious advantages, but with the mechanical means proposed by Messrs. Gattie and Seaman. In what follows we shall deal chiefly with the principles, not with the details that will be necessary in practice. Briefly, the problem is to transfer a parcel, bale or load of goods from any given position to any other given position in the clearing house. Suppose we have the arrangement shown in Fig. 1 in which there are a number of isolated divisional floors on the same level indicated at D_1, ... D_5, and each of these is divided up into bays. Every alternate divisional floor D_1, D_3, D_5, is surrounded by a moving platform or "belt," B_1, B_3, B_5, moving constantly in the same direction, as indicated by the arrows. Further, round the whole building or floor is another moving platform or "belt" which moves constantly in the direction of the arrow round the whole floor, and every part of this platform comes in close proximity to each divisional moving platform in turn. The arrival of goods trains and vans may be imagined to be below this whole structure; the contents of any van or railway goods wagon being hoisted bodily into one of the bays through a suitable well, the choice of the bay being governed by the convenience of the moment. Suppose that a batch of parcels has been delivered at M by one of the cranes, and each item has to be sorted and transferred to one of the various points of the main floor A, from whence they are despatched to their various destinations. It may be desired, for example, that all parcels, or goods of any sort, for Croydon shall be brought to the point N. Now it is clear that four transfers will suffice to bring a parcel from M to N. All that is necessary is, first, to transfer the parcel or bale to the divisional belt B_5, thence to transfer it to the main belt when the two are in proximity, next to transfer from the main belt to the divisional belt B_1, and finally to the point N. Hand manipulation in this way would not be much of an advance, and we have therefore to consider the mechanical method of doing the transfers. This may, naturally, be sub-

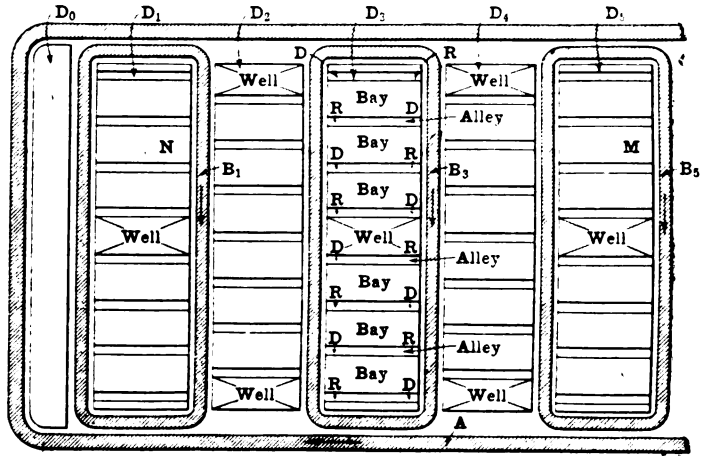

FIG. 1.—DIAGRAM OF FLOOR WORKED BY BELTS.
$D_0 \ldots D_5$, Divisional Floors; B_1, B_3, B_5, Divisional Belts; A, Main Belt; R = Receiving Point; D = Dispatching Point.

divided into the means of effecting the actual transfer and the means of assuring that the transfer from one platform to another shall take place at the exact moment desired. These we shall consider separately.

Means of Transfer.—In order to render the operations definite, the moving platforms consist of a series of trucks, or "truckers," as Messrs. Gattie and Seaman call them. Each parcel is placed on an iron tray, and this tray is transferred as a carrier whenever a transfer is made from a floor to a trucker or from a trucker in one platform to a trucker in the other platform. The tray is mounted on ball-bearing castors so that it will move easily in any direction. In a large clearing house the top of each trucker in the sorting hall would be, say, 5 ft. long and 4 ft. broad, and each tray would be the same size and designed to carry 5 cwt.; but shunters (*i.e.*, shunting trays) would be much larger and would carry 10 tons, and would be manipulated in the same way. Under the conditions assumed, each tray would be brought into a definite position at the point M, and would be transferred at the right moment to an equally definite position on an empty trucker of the belt B_5, later transferred to a trucker of main belt A, then to the belt B_1, and finally transferred to the floor D_1 at N. Now, since the trucker is moving continuously at, say, 3 miles per hour, the motion given to the tray must be in such a direction as will enable it to assume the speed of the plat-

Digitized by Google

form, and must also be transverse. Thus an oblique motion is necessary. This motion is obtained by having transfer rollers whose upper surface is slightly below the under surface of the tray. These rollers can be magnetised, and if a steel tray is above them when so magnetised they become attracted by the bottom of the tray, and thus any motion of the rollers is transmitted to the tray. Fig. 2 shows the arrangement of transfer rollers on a trucker seen in plan, and Fig. 3 is an end elevation of a trucker. These do not necessarily show the construction that would be adopted, but they serve to show the principle. It will be seen by Fig. 3 that the motion of the trucker causes a vertical spindle to rotate, carrying a bevel

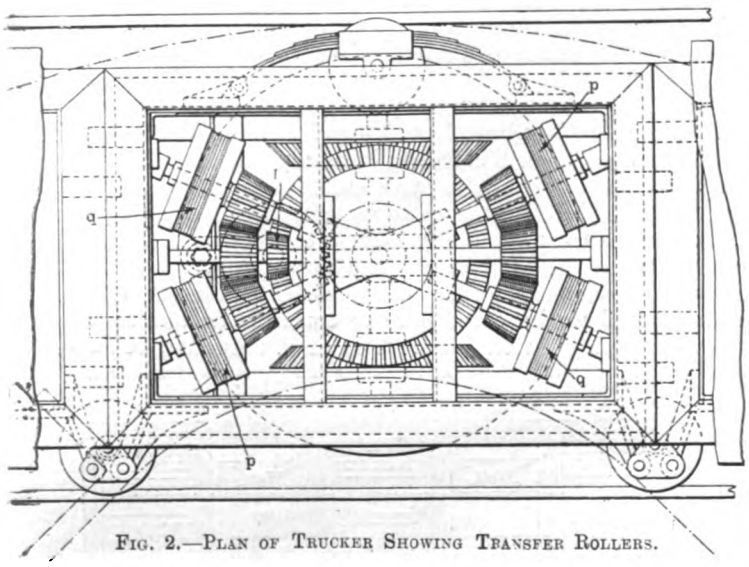

FIG. 2.—PLAN OF TRUCKER SHOWING TRANSFER ROLLERS.

wheel which gears with a pinion *n* (Fig. 2); and the spindle on which this is mounted drives the two pairs of transfer rollers *p.p* and *q.q*. This drive is coupled up through the medium of an electric clutch. The two rollers of either pair are excited in series, but only one pair would be in use at one time (although both would be rotating), the choice depending on the direction of motion of the trucker to give the necessary oblique motion. At the dispatching point M only one pair of rollers is required, and these are worked, also through an electric clutch, by shafting in the bay so as to run at the same speed as those on the trucker.

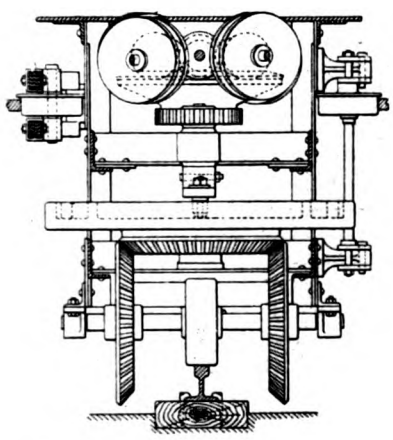

FIG. 3.—ELEVATION OF TRUCKER.

The transfer is, of course, complicated by the motion of the trucker. Thus in Fig. 4, if AB is the transverse velocity, BC the velocity of the trucker, then AC is the resultant velocity to be given to the tray. If the dispatch bay and the trucker are as shown diagrammatically in Fig. 4, the motion of the latter being shown by the arrow, then the rollers in the bay must be placed obliquely, as shown, and the rotation must be towards the trucker. On the other hand, the rollers used on the trucker must be those giving motion in opposition to the motion of the trucker itself, though the other component must still be in a direction away from the dispatch bay. For landing the tray the obliquity of the rollers would be reversed. Actually, it is not a case of uniform motion of the tray, because a certain acceleration at starting and deceleration at the finish must be allowed. Consequently, what takes place is that the rollers on both dispatch bay and trucker are clutched and energised at the same moment, and rotate while the trucker is passing over a certain distance, but the speed of the rollers is brought up gradually at the beginning and reduced gradually at the end of this travel by means of a cam arrangement, or some equivalent. The trucker is provided with wiping contacts, so that when these contacts are made the rollers are electrically in series and will work together if the other conditions permit.

Since the main belt runs at 6 miles per hour, *i.e.*, at double the speed of the divisional belt, the transfer from a divisional trucker to a main trucker, or *vice versa*, is made in the same way and under the same conditions, the relative motion being the same.

The Control.—It will now be seen that the automatic operation reduces itself to the closing of electric circuits at the desired moment. This is effected by a species of controller, or what is better termed a "register". It must be remembered that each bay and each trucker are provided with a number

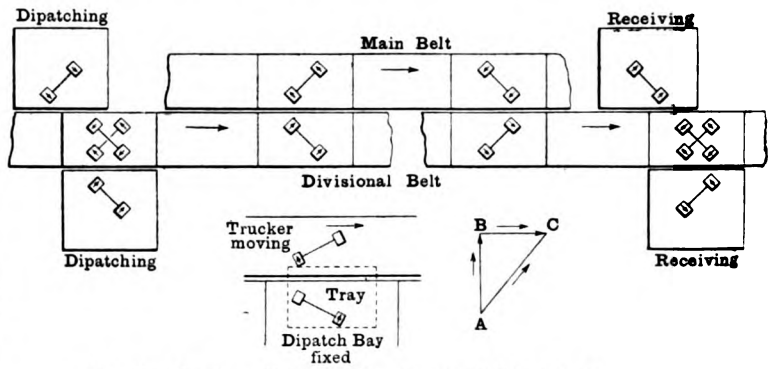

FIG. 4.—DIAGRAM SHOWING DIRECTION OF MOTION OF TRANSFER ROLLERS.

of rubbing contacts. Suppose, now, that each trucker while in its engaged position, *i.e.*, having a load on board, carries a register which moves one step forward each time a trucker makes contact with a bay. Then it is clear that by setting the register back to a suitable number, say, 5 from zero, the trucker will travel to the fifth bay before the register is brought back to zero, and if the connections for this position are suitably arranged, a transfer will take place at the bay following the fifth.

It is impracticable, however, for registers to be set by hand on each moving trucker, and therefore registers are provided at each dispatch point, and the setting of these is automatically transferred to the registers on the truckers. This is possible by connecting the registers in series.

Before going further, it will be well to indicate the form of a register in greater detail. In principle, it may be described as a ratchet wheel operated by an electromagnet, according to well-known methods, as shown in Fig. 5. Let the wheel carry an insulating arm, A, which passes through two springs, S, forcing them apart. This may be taken as the zero position of the register. If it is moved round, the springs are in contact and a circuit can be completed through them. Let the wheel carry 20 teeth and suppose it is set forward 7 teeth from zero. This setting may be done by hand or by a series of impulses by passing continuous current through the electromagnet V intermittently, each impulse causing the register to move on by one tooth. Suppose this register to be at the dispatch point. There is a similar register on each trucker. The register on the trucker and that at the dispatch point are

Digitized by Google

so connected up that when the trucker makes rubbing contact with the dispatch bay they are in series with each other and with a source of alternating current of low frequency, such as 5 per second. In the case of the dispatch register the circuit is made through the spring contacts S, but in the trucker register this is not so. Assuming that the trucker register is at zero, as soon as the trucker makes rubbing contact both registers will move round rapidly until the dispatch register has come round to zero when the circuit will be broken by the springs S being forced apart. In other words, both registers will have travelled round 13 teeth, but whereas the dispatch register will have returned to zero the trucker register will still have to move through 7 teeth before its zero is reached. Since 7 was the original setting given to the dispatch register, we see that this setting has been transferred to the trucker register, and that it will have to make 7 contacts (*e.g.*, at 7 bays) before it gets to zero. It will be noticed that the trucker register is at 13, whereas the dispatch register was at 7, that is the complementary number, and it follows that a transfer so made must always give the complementary setting.

Since there are two moving platforms, it is necessary to have double registers, the component parts of which may be called the bay register and the belt register. The bay register is for counting the number of bays passed, and the belt register for counting the number of divisional belts passed en route. Suppose, for instance, that the dispatch point M is in the fifth bay of D_5 from the end of the divisional floor in the direction of travel of the divisional

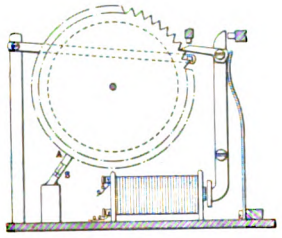

FIG. 5.—DIAGRAM OF REGISTER.

platform, then four bays must be passed before the main platform is reached, and the dispatcher therefore sets his register at 4. As there is one bay belt to be passed after the main belt has received the transfer before re-transferring to belt B_1, the main register is set at 1. If the point N is at the eighth bay, reached by travelling on the belt B_1 after being transferred from the main belt, the bay register must be set to pass six bays round the floor D_1. Hence, to take account of both floors, D_1 and D_5, the belt register is set at 7+4 or 11. The dispatcher therefore sets his combined register at 11 and 1 in circuit with the transfer roller control. If a loaded trucker passes nothing happens, but if a light trucker passes (*i.e.*, with its register at zero) then the settings of the bay and belt registers are transferred and the tray also. After leaving the dispatch bay the trucker makes contact at each bay, the contacts being short and connected to a source of continuous current. Therefore, at each bay the bay register moves forward one step, and after the four bays have been passed a transfer will occur to the main belt when any empty main trucker overtakes it and comes alongside. At the same time the setting of the main register is transferred by the action of alternating current as before through another circuit. Then, for the time being, the bay register is out of action. The main belt continues until the divisional belt B_3 has been passed, at which point the belt register moves on one, and having come to zero, a transfer to the belt B_1 is possible when the trucker reaches that part of the floor and overtakes a free trucker of belt B_1. When this transfer takes place the residue of the bay register is again transferred to the register of the new trucker by an alternating-current circuit, and the load travels round the divisional floor D_1 until the point N is reached.

It is well to notice that there is a point in which this description is not quite accurate. Since in transferring a register the complementary number results, it follows that after the first transfer from the dispatching point the bay register would show 11 points to run and the main register one point to run. But when the transfer to the main belt takes place there would be 7 on the bay register and 1 on the main register to be transferred. The transfer will, therefore, result in the numbers 13 and 19 (supposing the belt register wheel also to have 20 teeth). Consequently this second transfer does not give us what is required on the main register, but this difficulty is easily avoided by the dispatcher setting his register at 19 instead of 1. The complementary number on the bay register does not matter because it does not come into use again until after a third transfer, when the number 7 again results. In

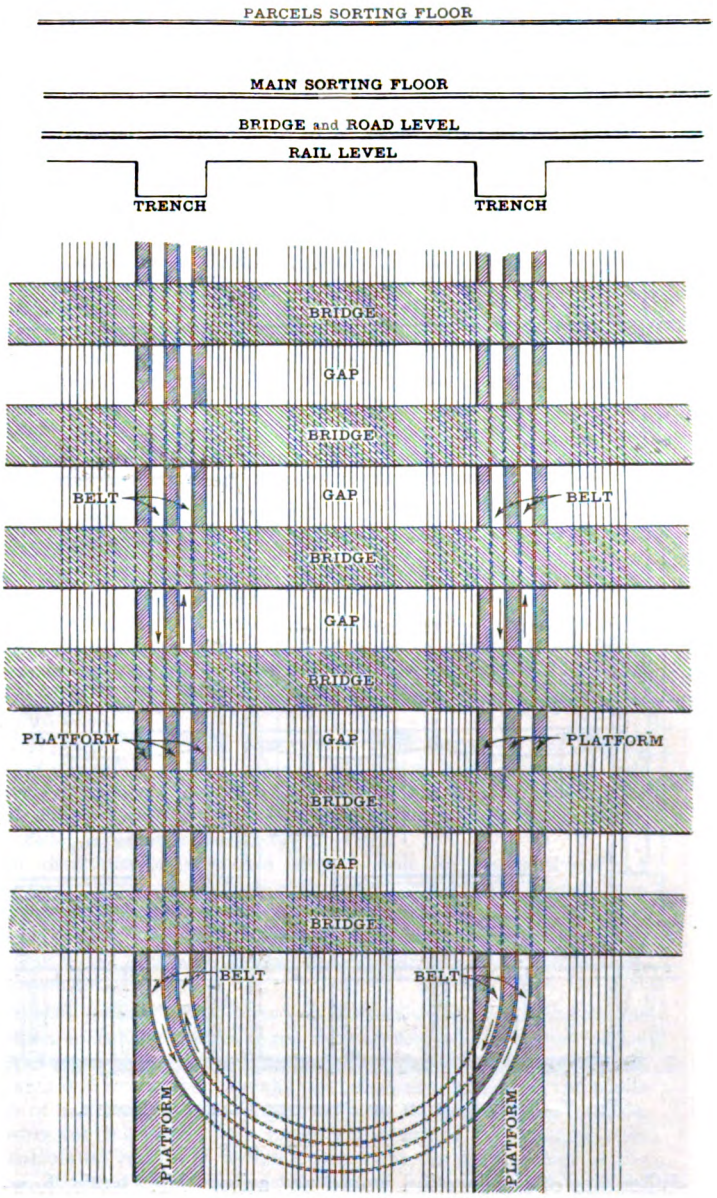

FIG. 6.—DIAGRAM SHOWING MEANS OF INGRESS AND EGRESS BY ROADS AND RAILWAYS, ALSO SHUNTING TRENCH.

practice this would all be arranged automatically by having a set number for every delivery point, and the same number would apply for dispatching from any point by setting the dispatching registers to suitable false zeros.

It may be mentioned that if the trucker in a divisional belt does not come in contact with a free trucker in the main belt, the loaded trucker merely travels round the floor, returning to the same point when a further opportunity occurs. The trucker is found to travel right round the divisional floor because its failure to transfer on to the main belt keeps its discharging circuits open.

Digitized by Google

The trays which arrive at the delivery points proceed very slowly to the dispatching points by the tray alleys. These alleys are operated by live rollers which can be brought to a standstill, and re-started at will by the operator. It is while trays are thus slowly proceeding between bays from receiving points to dispatching points that they are unloaded of the goods they have brought and reloaded with goods they are required to take away. These alleys are marked in Fig. 1, and it will be noticed that one end of each is used for receiving (marked R) and the other end for dispatching (marked D), so that the circulation of goods and trays is very simple. The large shunting platform in the sub-basement of the building is a large edition of those in the sorting hall.

Details of the Clearing House.—The system described is applicable in a general way to any establishment in which a large amount of sorting is carried on, though it is obvious that in the case of small parcels the machinery might be much less elaborate, because the weight per parcel would be small and

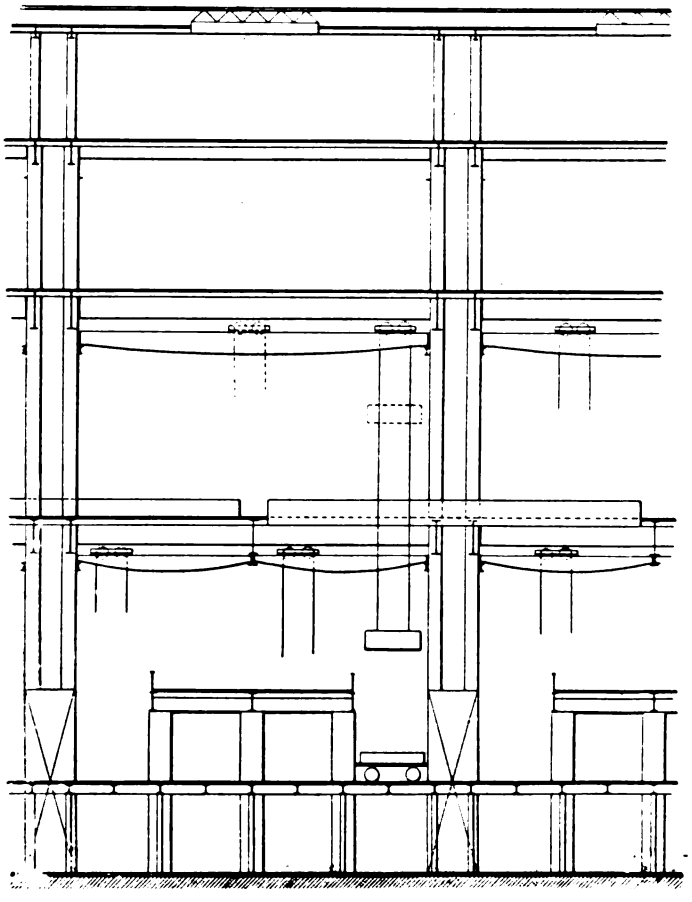

FIG. 7.—PART SECTION OF PROPOSED CLEARING HOUSE.

difficulties of acceleration would not arise. Mr. Gattie, however, is ambitious in his ideas, and therefore he discusses the possibility of handling all London goods (except, for the moment, coal and cattle) in a single building, which, by analogy with the method followed by bankers, he calls a goods clearing house. For this purpose he would erect one huge building, through the centre of which Clerkenwell-road would run. This building would be 1,144 ft. long by 440 ft. broad, and from crypt to roof 180 ft. high, with five water towers 208 ft. high.

All the railway lines would be connected with this building by means of three underground lines, 28 berths being laid in the basement of the building, as indicated in Fig. 6, which is a diagram showing the general lay out. The lowest level in the building is the crypt, where loads are retained, if necessary, pending the arrival of the appropriate train, and accommodation is provided here for 1,000 loads. Each of these loads is immediately available without the disturbance of any other load; this feature being a marked advantage on the system of any existing goods station.

Above the railway berths, and running at right angles to them is a series of 12 bridges, each 44 ft. wide, affording access for road vehicles.

The method adopted would be to provide vehicles, both railway and road vans, with detachable containers. These would be hoisted by means of cranes as soon as the vehicle came into position, and the contents would be distributed by means of the automatic apparatus, or, if required, the container would be transferred immediately on to another railway line. Shunting would be avoided by what Mr. Gattie terms "trenching." The loads would be hoisted by cranes and lowered into the trench furnished with two moving platforms moving in opposite directions, so that loads deposited by a crane at one point would be conveyed to any other point, and thus placed beneath any other crane in the building. This trench with its moving platforms would cross under the railway sidings at each end of the building, as indicated in Fig. 6.

Fig. 7 shows part of a longitudinal section of the clearing house. The building is supported by structures of four steel columns, each 4 ft. in diameter. The lowest level is the crypt, to which reference has already been made; above this are the railway tracks. Above these again are seen the road bridges (in section) surmounted by a series of travelling cranes. Above the bridges comes the first floor, which is the great sorting hall, where the heavy goods (*i.e.*, up to 5 cwt.) would be sorted. This floor is similar to that shown in Fig. 1. But there are 48 bays to each divisional floor, and the number of divisional floors is six. It will be noticed that the bays are staggered so as to utilise the belt to the best advantage. The divisional floors are 88 ft. by 440 ft., and are provided with wells through which the goods are hoisted. The system of cranes would deliver from the railway tracks to the roadways or vice versa, or to this heavy sorting floor. From this floor the small parcels are transported by belts to the floor above, which is reserved for this lighter sorting work. The top floor contains offices, workshops and other accommodation, and as the roof covers 10 acres it is fitting that such an area should be laid out as a garden. The cost of the whole scheme, including 2 miles of tunnels for railway approaches, is estimated at 54 millions sterling.

In concluding our description of this interesting scheme we may mention that the design of the proposed plant for handling the goods has been examined by Sir William Preece, who states that, in his opinion, the proposal is sound in principle, and states further: "We also think that the mechanical and electrical arrangements are practical in conception, although probably some modification in detail will be found advisable after experience of working has been obtained." Messrs. Waygood have also expressed themselves satisfied with the practicability of the scheme.

Hydro-electric Extensions in Canada.—The "Canadian Electrical News" in a recent issue gives particulars of the proposed second power station of the Shawinigan Water & Power Co. This station will be situated near the present generating plant at Shawinigan Falls, on the St. Maurice River, about 85 miles from Montreal, and will be designed for a capacity of 75,000 H.P., as against 55,000 H.P. in the case of the existing station. It is stated that the Company's transmission lines, which are of aluminium carried on wooden poles, are at present the most extensive in Canada, exceeding a total of 400 miles. For transmission to Montreal the current, which is generated at 2,200 volts, is stepped up to 50,000 volts; 3,000 H.P. is supplied to the Montreal street railways, and 15,000 H.P. to the Montreal Light, Heat & Power Co. It is of interest to mention that the Shawinigan Company supply 25,000 H.P. of water-power (undeveloped) to the Northern Aluminium Co., and 14,000 H.P. of water-power to the Belgo-Canadian Pulp & Paper Co. The greater part of the above power is obtained at a second dam about a mile up the river.

RECENT ADVANCES IN PYROMETRY.*

BY R. S. WHIPPLE.

Summary.—The author discusses gas thermometry, resistance thermometry, thermo-electric pyrometry and radiation pyrometry, describing recent developments in each subject. He finally refers to the question of standardisation, and suggests that the national physical laboratories in each country should supply small quantities of pure metals for the determination of fixed temperatures.

The science of pyrometry has made such strides during the last few years that it may be helpful to consider briefly the work that has been carried out within comparatively recent years. As pyrometric methods are being so largely used in all industries, it is well to examine the present position of the fundamentals on which the science of pyrometry is now based.

Gas Thermometry.—Referring first to the gas thermometer, the final reference in all thermometry, a great deal of work had recently been devoted to the extension of the gas thermometer scale. Holborn, at the Physikalisch-Technische Reichsanstalt, by means of a bulb of pure iridium, has been able to extend the temperature measurements with his gas thermometer to 1,600°C. This thermometer scale, which is now generally used as the basis of high temperature measurements, is officially stated to have a probable error of 2 or 3 deg. between 300 and 1,150 deg., and of 10 deg. between 1,150 and 1,600 deg. The great difficulty in gas thermometry is to find a material of which a bulb may be made which will hold an expanding gas without loss or change through a long range of temperatures and yet will permit of accurate measurements of the pressure-volume relations within the bulb. Day and Clement overcame this great difficulty by arranging that the bulb should be surrounded by nitrogen at the same pressure as that inside the bulb. This checked any tendency of the gas to diffuse through the walls of the bulb and at the same time prevented any deformation of the bulb due to internal pressure. A further important advantage was the fact that much greater pressures could be employed. In this way it was possible to make the instrument three times more sensitive than any other gas thermometer. It is interesting to note that Dr. Day believes that in the future porcelain bulbs will no longer be used in gas thermometry, partly because of the uncertainty in determining their coefficient of expansion and partly owing to their porosity. In the last report of the National Physical Laboratory it is stated that Dr. Harker, in order to measure extremely high temperatures, proposes to make a gas thermometer bulb of some of the rare earths, such as those used in making Nernst filaments. If this project is carried out a great deal of light may be thrown on high temperature gas thermometry; but the difficulties to be contended with are very great.

Resistance Thermometry.—There is not any striking advance to report in this branch of thermometry. A valuable Paper by Dr. Harker on the "High Temperature Standards of the National Physical Laboratory"† gives the results of a series of comparisons made between the resistance and thermo-junction standards and the nitrogen gas thermometer up to 1,000°C. These results entirely justify the use of Callendar's parabolic formula up to 1,000°C. Waidner and Burgess‡ have since confirmed Harker's results in an investigation of the behaviour of resistance thermometers made of platinum wires of varying degrees of purity.

In the construction of resistance thermometers some improvements have been introduced, the most important being that due to Dr. Haagn,§ who suggested to Messrs. Heraeus the construction of a thermometer in quartz, the wire being wound on a rod of quartz and protected by a very thin tube of quartz fused over it. This thermometer can be made as small as 25 mm. long and 3 mm. in diameter, and yet be comparatively robust. By this arrangement the wire is protected from the injurious effect of gases and mechanical strain; it also very quickly attains the temperature of the surrounding medium. It is, however, handicapped by the drawback that quartz devitrifies if exposed for any length of time to temperatures as high as 1,000°C.

Two new methods of winding the thermometer coils for avoiding strain on the wires are shown in the Paper by Waidner and Burgess previously referred to; one in which, by means of a modified form of mica frame, a flexible mounting is given to the wire, and the other, due to Northrup, in which stouter wires in the form of a spiral without any support are employed. Prof. Callendar has also designed some very sensitive resistance thermometers for medical work. In America the Leeds & Northrup Co. have lately introduced a recorder for use with resistance thermometers, and also a direct-reading instrument or ratiometer.

Thermo-electric Pyrometry.—In this branch of the subject most workers appear to have devoted their efforts to: (*a*) Increasing the purity of the metals employed in the platinum thermo-couples; (*b*) producing cheaper or base metal couples, the large increase in the price of platinum having produced a demand for such couples; (*c*) improving the methods of measurement with thermo-couples.

(*a*) Great steps have been made comparatively recently in the production of pure and homogeneous metals for standard thermo-couples, the firms of Johnson, Matthey & Co., of London, and Heraeus, of Hanau, having sunk a considerable amount of capital in large ingots of pure platinum, platinum 10 per cent. rhodium, and platinum 10 per cent. iridium, for this purpose. In the case of a sample supplied for thermo-couples to the National Physical Laboratory by Messrs. Johnson, Matthey & Co. the analysis of the platinum-rhodium alloy was as follows: Platinum = 89·9, rhodium = 8·98, both being directly determined and no trace of any other metal being discovered.

The ingots owned by Messrs. Johnson, Matthey & Co. have been found to be exceptionally homogeneous, and Messrs. Heraeus have now been able to repeat their standard of purity for some time. So that, as a result of the work of these two firms, it is possible to obtain a second thermo-couple similar to one previously obtained, and that may be used without introducing any serious error on the same galvanometer or recorder.

It has been known for some time that platinum thermo-couples deteriorate in an atmosphere of hydrogen, but it has not been possible to account for a large number of the failures. In the Paper by White* it was shown that the main source of error in thermo-elements is in homogeneity, by the removal of which, in most cases, far greater accuracy may be attained than has hitherto been realised. It was also shown that the iridium slowly sublimes from the platinum-iridium side of a couple and enters into combination with the platinum side, thus slowly reducing the E.M.F. given by the couple. This sublimation has been found to commence at 900°C. and to become serious at 1,200°C.

Iron has undoubtedly a disastrous effect on platinum, and the destruction of large numbers of couples may be put down to this cause. Annealing a low-reading thermo-couple to a temperature of 1,200°C. will frequently restore it to its original E.M.F. When the use of contaminated elements is necessary, fair accuracy can still be obtained if the defective couples are frequently compared with standard ones.

(*b*) A large number of wires have been suggested for making cheaper thermo-elements. Onnes and Clay have employed gold and silver elements for very low temperatures with success, this couple showing itself at −253°C., as read on a hydrogen thermometer, to be twice as sensitive as constantan-steel.

The most satisfactory base metal couple for temperatures not exceeding 700°C. is undoubtedly copper-constantan (constantan = 60 per cent. copper, 40 per cent. nickel), and this couple has been used in several scientific researches. Amongst other couples may be mentioned iron-constantan, iron-nickel, iron-nickel chromium, copper-nickel.

A useful book by Prof. Pécheux† has lately been published on the thermo-couple. In this he urges the adoption of the copper-nickel couple for use up to temperatures of 900°C., and he also shows that although it is impossible to make one parabolic formula fit the whole range of usefulness of the couple, yet with the aid of three formulæ covering varying parts of the range, the observed results agree with the calculated results to within 1 deg. over the greater part of the scale. My own experience shows that it is extremely difficult to obtain homogeneous wires, and therefore, for accurate results, it is necessary to calibrate every individual couple, and even then the calibration may be found to have seriously altered if, by any chance, the couple has been overheated or perhaps over-annealed.

For accurate work it is customary to maintain the cold junction of a thermo-couple at 0°C., but not infrequently, in what may be called semi-scientific work, it is not easy to control the cold junction temperature. Although it has been customary to halve the difference between the temperature of the head of the thermometer and 0°C. and to add this quantity to the obtained hot junction temperature, provided the cold junction correction does not exceed 50°C., yet this is incorrect, as the relation of the E.M.F. to temperature is not a straight line. This has been fully discussed by C. Offenhaus and

Digitized by Google

Ernst N. Fischer,* who show that the correction depends on both the hot and cold junction temperatures and the particular couple. Briefly, they show that the true temperature of the hot junction is not, starting with the needle at zero (the cold junction having the temperature of the room), the temperature which corresponds to the millivolt reading, but is found by adding the number of millivolts which corresponds to the temperature of the cold junction to the millivolt reading.

(c) For accurate work the conditions imposed upon a potentiometer for use with thermo-electric couples are very exacting, and may be grouped as follows: (1) If possible, temperatures up to 1,600°C. must be read to 0·1°C. with a platinum, platinum-rhodium element, 0·1°C. corresponding to about $\frac{1}{1000000}$th of a volt. (2) The potentiometer coils must be unaffected by leakage from external circuits. (This is important where, as is now generally the case, the thermo-couple is being used in a furnace which is electrically heated by heating coils the P.D. in which may be 100 volts or more, any leakage to the potentiometer coils introducing serious errors.) (3) Manipulation must be simple in order that quickly altering temperatures may be followed.

To meet the above conditions various potentiometers have been designed, amongst the most important being those designed by Dr. White,† Dr. Harker‡ and the Cambridge Scientific Instrument Co.§ The instrument designed by Dr. White differs from the other two in that no bridge wire is employed, the rapidity of action being obtained by switches and a direct-reading galvanometer. In the instrument designed by Dr. Harker and also in that designed by the Cambridge Scientific Instrument Co. the bridge wires are kept as short as possible, being placed in series with a continuous coil of many sections. In the former instrument these sections are introduced by means of connectors and mercury cups, in the latter by a switch and contacts. The maximum E.M.F.s that can be measured are 21 and 30 millivolts respectively, and the minimum, by estimation, 1 microvolt.

Several recorders of various types have been introduced for use with thermo-couples; amongst others must be mentioned those by Pellin, Siemens & Halske, W. H. Bristol and the Cambridge Scientific Instrument Co.

In connection with the last-mentioned instrument some experiments have lately been tried with a view to increasing the stability of zero. It has been found that a phosphor-bronze wire reduces the creep from half to one-third that which would be given by the same wire rolled as a strip.

Radiation Pyrometry.—The last few years have witnessed great progress in this, the latest, branch of pyrometry. The temperature of a hot body may be estimated either from the visible light emitted or from the thermal effects of the longer infra-red waves. The intensity of the light emitted by a hot body varies enormously with the temperature, and therefore at the first glance one would assume that the easiest way to a temperature would be photometrically to compare the light emitted by the hot body with that emitted by a second hot body at a definite temperature; but, unfortunately, all bodies at the same temperature do not emit the same amount of light. Kirchoff first propounded the idea of a "black-body" as being a body which would absorb all radiation falling upon it and would neither reflect nor transmit it. He also showed that the radiation from such a body is a function of the temperature alone. Wien and Lummer were the first to make a scientifically so-called "black-body" furnace, although this was much improved by Lummer and Kurlbaum in 1898 by the addition of electrical heating. It may be noticed in passing that very often furnaces employed in industrial operations closely approach black-body conditions.

It is found that the apparent temperature of any material when away from black-body conditions always bears a fixed relationship to its true temperature, this apparent temperature being called its "black-body" temperature. It is thus very important to know the relationship between the radiation emitted and the temperature, and a great deal of mathematical and practical work has been devoted to this object. Stefan was the first to state that the energy radiated was proportional to the fourth power of the absolute temperature. Boltzmann later propounded the same law from thermo-dynamic reasoning, assuming the existence of light pressure. This law has since become known as the Stefan-Boltzmann radiation law—$E = K(T^4 - T_0^4)$. When the radiation from an incandescent body passes through a non-absorbing prism it is spread out as a spectrum and the energy corresponding to the different wave-lengths may be determined by means of a bolometer. Such experiments have shown that the greater part of the energy is found in the infra-red part of the spectrum. It is also found that if the particular wave-length having maximum energy for a given temperature of the radiating body were determined, and if the temperature were then raised, the wave-length of maximum energy was displaced towards the shorter wave-lengths. This displacement with change of temperature is illustrated by the now well-known energy curve of Lummer and Pringsheim.*

Wien found that as the temperature of a hot body is changed the wave-length having the maximum energy will be changed, so that the product of the wave-length λm and the corresponding absolute temperature T is a constant. If T increases, λ shifts towards the shorter wave-lengths. Combining the above relation with the Stefan-Boltzmann law, he was led to the constant $E_{max.}T^{-5} = \text{constant}$, in which $E_{max.}$ indicates the energy corresponding to the wave-length of the maximum energy and T is the absolute temperature of the radiating source. Planck has also propounded a formula which represents the results for certain regions of the spectrum and for certain temperatures somewhat better than the Wien formula, the calculated values agreeing extremely well with the observed.†

A basis on which to found radiation measurements being thus obtained, it has been a comparatively easy matter to design instruments for measuring the radiation. The first satisfactory radiation pyrometers were photometric—that is to say, they were arranged to match the luminous radiation obtained from an incandescent body against that obtained from a standard lamp. The Chatelier, as modified by Féry, and the Wanner pyrometers are the most successful photometric pyrometers. In both cases mono-chromatic light is matched against that obtained from a lamp, in the former from an amyl-acetate flame, in the latter from an electric incandescent lamp. A considerable amount of light is lost in the optical system of the Wanner, thus preventing temperature measurements below 900°C., and for that reason, as well as for the openness of scale of the Féry pyrometer, the latter is to be preferred. Féry has recently modified this instrument by the addition of extra neutral tinted glasses, so that the range is largely extended. The instrument as now arranged is particularly suitable for determining the temperature of incandescent lamp filaments, the electric arc, &c. On the other hand, the instrument is not so portable as the Wanner. The Holborn-Kurlbaum pyrometer has proved itself a useful tool in the hands of the observers at the Reichsanstalt and at the Bureau of Standards. The only instruments using the total radiation from a hot body are the Féry and Thwing pyrometers. Féry's first model consisted of a lens (preferably fluorite) which focussed the radiation received on to a small thermo-electric couple, the E.M.F. generated actuating a sensitive galvanometer. Unfortunately, the lens absorbed a considerable quantity of the radiation, especially at the low temperatures where a great part of the energy exists in the form of long wave-lengths, and the pyrometer was, therefore, only suitable for high temperatures. Féry afterwards modified the instrument by substituting a concave mirror to focus the radiation instead of the lens, and this largely increased both the range and the sensibility of the instrument. Its sensibility has since been further increased by the substitution of a more sensitive and efficient thermo-couple, the greater E.M.F. obtained enabling pivoted galvanometers to be employed in place of the more delicately suspended instruments. By employing a comparatively delicate galvanometer it is possible to determine temperatures with this instrument below the boiling point of water.

Féry has since introduced a third form of this pyrometer, in which the radiation is concentrated on to a small bi-metallic spiral, carrying an aluminium pointer. As the temperature of this spiral increases it unwraps itself, moving the pointer over a scale. This simple form is being found useful in works where it is desirable to avoid the complication of a galvanometer.

Some interesting tests were recently made at the National Physical Laboratory on the absorption of the receiving mirrors in these instruments, and it was found that they reflected about 96 per cent. of the total radiation falling upon them. It was also found that a slight film of oxide on the gilded surface of the mirrors made no serious difference to the amount of radiation reflected, as the greater part of the energy exists in the form of long wave-lengths which the tarnished mirrors reflect without difficulty.

Thwing‡ lately has introduced a pyrometer in which the radiation is reflected on to a thermo-couple by a deep conical mirror, a series of diaphragms being arranged in a tube so that a fixed cone of rays always falls on the mirror.

As previously stated, optical pyrometers are calibrated in terms of the radiation emitted by a black body, but the temperature as measured by them will depend on the nature of the hot body under observation. It is, therefore, necessary to know the "black-body

temperatures" of a material at a given temperature in order to obtain the real temperature. A great deal of work has been done on this subject, more particularly on the black-body temperatures of platinum and molten copper. But it is much to be regretted that no authoritative work has yet been carried out on the black-body temperatures of molten iron and steel.

Standardisation.—The question of standardisation is of great importance to all users of pyrometers. The various national physical laboratories have apparatus capable of testing closely up the scale to 1,500°C., and have also one or two other points of reference up to the temperature of the arc. It is interesting to note that the tendency of recent workers is to adopt the melting points of pure metals as the standards of reference, several of the melting pionts being known to a high degree of accuracy. Unfortunately the metals cannot be obtained commercially sufficiently pure to guarantee an accuracy of 1°C. at the higher temperatures, but if an accuracy of 1 to 3 deg. is sufficient, then Kurlbaum's best materials will answer the requirements. It is hoped that in the near future the National Physical Laboratory, or some similar institution, will be able to supply small quantities of pure metals the melting points of which have been carefully studied.

The author finally gives a list of the most satisfactory standardisation points.

AN IMPROVED METHOD OF SORTING INCANDESCENT LAMPS.*

BY K. KEIL.

The sorting of lamps is a most important operation, seeing that nowadays lamps of 16, 25 and 32 c.p. are required for a series of very definite voltages, differing often by a single volt. This requires very careful work, and the following graphical solution is given as the outcome of a considerable experience in dealing with both metallic and carbon filaments, the test lamps having been taken quite at random from a very large stock.

The mean horizontal candle-power and the number of watts taken at different voltages are first determined, and plotted on a curve. Table I. gives figures for Osram lamps. The observed candle-power, as noted in column 3, satisfies the equation $y = a \cdot x^b$, where x is the voltage, y the candle-power, and a and b are constants. The calculated value of b is given in column 4. Thus if E_1 and E_2 are two voltages, and L_1 and L_2 the corresponding candle-power, we have

$$\left(\frac{E_1}{E_2}\right)^b = \frac{L_1}{L_2} \quad \text{and} \quad b = \frac{\log L_1 - \log L_2}{\log E_1 - \log E_2}.$$

The small differences in the values of b are doubtless due to errors of observation, the mean value being probably correct. The mean value for 16 c.p. was found to be 3·88, for 32 c.p. it was 3·81, and for 50 c.p. it was 3·85, there being in these cases no great difference, and 3·85 can probably be taken as the nearest approximation. We may therefore assume that the candle-power of an Osram lamp varies as the 3·85th power of the voltage, and on the basis of this assumption the calculated candle-power is given in column 5, and curves can be constructed. From the observed values of the watts taken by the lamp at different voltages, it seems that the number of watts varied with the 1·59th power of the voltage. The observed values are given in column 6, and the calculated values in column 8. From this we see that there is a direct connection, which can be expressed in a formula, between the voltage and the candle-power, and also between the voltage and the watts taken by any particular lamp. Similarly there is also a connection between the voltage and the efficiency, as expressed in watts per candle-power, which may be formulated as follows, viz., the efficiency of an Osram lamp, expressed as watts per candle-power, varies inversely as the 2·26th power of the voltage. The figures for the Bergmann filament are slightly different; the candle-power is proportional to the 3·98th power of the voltage; the watts, taken by the lamp, to the 1·68th power, and the watts per candle-power inversely to the 2·3rd power. Thus the Bergmann and the Osram lamps give very similar results, and this is obviously due to the fact that essentially both consist of tungsten, and such small differences as can be noticed are doubtless due to slight variations in the method of manufacture.

With carbon filaments, things are rather different, and the exponential coefficient does not remain constant, as in the case of tungsten lamps. When dealing with the connection between the candle-power and voltage, the value of the exponent b varies from 7·87 to 4·23, and in the neighbourhood of the normal voltage its value is 6·3, which is about twice its value in the case of the metallic filament. The watts taken by the lamp vary as the 2·18th power of the voltage; in the case of the connection between the watts per candle-power and the voltage, the value of the exponent b varies from −5·72 to −2·05, its value at the normal voltage being −4·1. In Table II., all the values of b are collected together and arranged systematically. Here b_L is the exponent for the candle-power, b_A is the exponent for the total watts taken by the lamp, b_S is the exponent for the watts per candle-power.

* Abstract of an article in the "Elektrotechnische Zeitschrift," April 28, 1910.

CHARACTERISTIC CURVES FOR OSRAM LAMPS BETWEEN 100 AND 130 VOLTS.

These figures can be regarded as characteristic of the various lamps. A simple calculation shows that the resistance of the lamps can be deduced from the figures already given. Thus, in the case of the Osram lamp, the resistance varies as the 0·41th power of the voltage, in the Bergmann lamp it varies as the 0·32th power, and in the carbon filament it varies inversely as the 0·1th power.

The question now arises as to how these figures are to be used in the sorting of lamps. Let us suppose that we are dealing with a batch of Osram lamps to be run at voltages between 100 and 130. Here all the measurements can probably be conveniently made at 115 volts, and it is an advantage to use, as a standard, a lamp which has been calibrated at 115 volts. For all Osram lamps, with voltages between 100 and 130, the appended curves will be used. Let us suppose a lamp to have been tested at 115 volts, and its candle-power has been found to be 28·3, and its total watts 31·1. Its efficiency is therefore 1·1 watts per candle-power. In the curve the ordinate at 115 volts corresponds to 1·1 watts per candle-power. This ordinate measures 100 mm. But the lamp in question is intended to be run at an efficiency of 1 watt per candle-power, and to this the corresponding ordinate will be $\frac{1 \cdot 0}{1 \cdot 1} \times 100$ mm., *i.e.*, 90·9 mm. It is therefore necessary to find the point on the "watts per candle-power" curve which has an ordinate of this length. The corresponding abscissa will give the voltage at which the lamp must be burnt, which is in this case 120·2 volts. In order to find the candle-power of the lamp, the ordinate of the "candle-power curve" corresponding to this voltage must be found and measured on a proper scale. At 115 volts the candle-power was 28·3, so that 28·3 candle-power corresponds to an ordinate of 100 mm. The ordinate on the "candle-power curve" corresponding to 120·2 volts

Mean :	3·85	1·59	−2·26	3·98	1·6	−2·3	Mean :	7·87 to 4·23	2·18	(−5·72) to (−2·05)

measures 118·5 mm., and the value of the candle-power at this voltage will therefore be $\frac{118·5}{100} \times 28·3$, *i.e.*, 33·5 c.p. The lamp in question may therefore be taken as giving 32 c.p. at 120 volts.

It may appear at first sight as though the proposed method was likely to be rather wearisome. A little practice is sufficient to prove that it can be worked very quickly, and that it allows a much more exact sorting of the lamps than has been hitherto possible. Lamps are often labelled as giving 25 c.p. at a given voltage, whereas they are found in practice to give 30 c.p. and even more; sometimes, on the other hand, they give less than their nominal candle-power. Cases of this kind would be impossible if the proposed method were properly applied.

THE WIRING OF THE NEW BUILDING OF THE INSTITUTION OF ELECTRICAL ENGINEERS.

The step taken by the Council of the Institution of Electrical Engineers to provide the Institution with a home of its own by taking over the building of the Royal College of Physicians and Surgeons on the Victoria Embankment has already been dealt with in these columns. The work of reconstruction of the interior of the building has proceeded apace, and it is hoped that by the time the 1910-1911 session opens the whole of the business of the Institution will be conducted in the new quarters. The original building was wired for electric light, but as this installation was carried out some quarter of a century ago it was found quite unsuitable for the present purposes of the altered building. The work of remodelling has, therefore, included the complete re-arrangement of the electrical circuits and the provision of a supply of energy for both lighting and power purposes.

The consulting engineers for the re-wiring of the premises are Messrs. Handcock & Dykes, who were instructed to prepare a complete specification which would bring the installation entirely up to date. From a perusal of this specification it is evident that the consultants have done their utmost to bring the installation into line with modern wiring developments, and from an inspection of the work we can confirm the high standard aimed at in the specification. The specification gave the contractors practically a free hand to choose from among the various recognised systems of wiring. After consideration the contractors decided to use screwed steel barrel for all the main wires and tinned brass tubes for sub-distribution purposes as being most suitable for the carrying of the circuits round the old walls of the building. With the exception of the basement, the whole of the wiring is concealed, and this system of tubing was found to be very adaptable to the process of sinking below the level of the plaster; at the same time, by the adoption of a scheme of easy bends in the tubing, drawboxes were dispensed with and the insulated wires could be pulled through between the switch and the light points after all decorative work was completed. The whole of the sub-circuit wiring has been installed upon this plan, with the result that there is not a single draw-through box at any point in this portion of the installation. The contractors for the entire installation were Messrs. Drake & Gorham, Ltd.

The tinned brass tube or Kalkos system of wiring was described in THE ELECTRICIAN "Industrial Supplement" for October, 1907, and since its introduction at that time it has been installed in many large and important buildings. We may recall here the main features of the system, namely, the brass tubes heavily tinned inside and out, the sweating up of all switch, ceiling and bracket boxes and the novel adjustable ring in all the boxes, by means of which the level of the particular accessory, either switch, ceiling rose, or wall plug can be altered to suit the requirements of either flush or surface wiring. The general principle of the system remains the same, and its application has been considerably amplified in accordance with the greater experience obtained with its practical application.

The supply of energy for the new Institution building is being given by the Savoy Hotel (Ltd.), whose power-house is immediately adjoining, at a pressure of 100 volts, two-wire, the service being in duplicate. The cables enter the building at two distinct points, and comprise, in each case, two pairs of 19/12 lead-covered V.I.R. mains coupled up to the service at the point P (Fig. 1) in the basement. One

pair has been disconnected from the existing fuseboard at B and extended by means of a new pair of cables through a 75-ampere cast-iron switch fuse to a new circuit fuseboard at N. The other pair has been run into a new board at the point C to supply a portion of the circuits of the Royal College of Physicians, and also into a board at E from which a supply is given to the front portion of the Institution building. The board at N is three-way, and controls the circuit to the lantern room, lecture hall and the corridor at back of the lecture hall. The board at E is seven-way, and controls the circuits for the tea and smoking rooms, lecture lantern, basement corridor, first floor west and east, and two circuits for the cornice lighting in the lecture hall. The working current of the N board fuses is 25 amperes, and the fuses on board E work at 51 amperes in the case of five circuits and 25 amperes in the case of two circuits. The risers from these main circuit boards to the distribution boards have been run in screwed steel conduit of heavy gauge, and the cables are V.I.R. taped and braided.

The lay-out of the principal circuits in the building is shown in the diagrams (Figs. 1, 2 and 3). A reference to these will indicate the positions of the incoming cables, the main circuit boards and the principal distribution boards. Ample provision has been made for adequate and appropriate illumination of the various rooms, and wall sockets have been included at a number of convenient points in almost every room, but more particularly in the library.

Special circuits have been run for the lecture hall table lantern and to the lantern room overlooking the lecture hall. In the tea and smoking rooms three experimental wiring points have been provided, and these terminate in special cast-iron boxes sunk into the wall. Each box contains two single-pole enclosed switch fuses and two heavy pillar terminals with fly nuts to which temporary leads can be quickly connected. The boxes are fitted with plate glass and polished hardwood fronts which match the surrounding panelling.

Separate power circuits have been run to supply energy to a motor for the service lift from the basement to the tea-room. A pair of 7/18 mains has also been run in heavy gauge steel screwed conduit to a motor starter and regulating switch with no-volt release, and thence to a motor driving a 42 in. horizontal discharge ventilating fan. This latter has a capacity of 10,000 cubic ft. of air per minute against $\frac{1}{4}$ in. water pressure, and is employed for extracting the air from the lecture hall. The motor for this fan develops 1 H.P. and the speed is 300 revs. per min.

We were given an opportunity of inspecting the installationwhen the work of running the brass tubes was in progress. We were then shown how they had been planned out so that wires could be drawn from point to point without the use of draw-in boxes. Despite the fact that the wires travel round several bends this method was uniformly applied throughout. Photographs were taken at the time of installation, and Figs. 4, 5, 6, 7 and 8 serve to illustrate the manner in which the work was done. A minimum of tube is required, and also the smallest possible amount of cutting away of the walls and plaster.

The standard Kalkos boxes admit of the entry and exit of wires from any point on the side of the box, and also through the bottom of the box. The tubes in every case are sweated into special inlet and outlet pieces, which are bell-shaped and, therefore, avoid sharp bends. They also dispense with the

building was first erected, the plastering was carried out, and subsequently the wires were drawn in. There are no joints in the wiring, the looping-in system having been adopted throughout. This is according to specification, though, of course, it does not apply where flexibles or fittings wires require to be linked up to the wiring circuits. With fittings wires an ordinary soldered joint is made, and with flexibles the connection is effected with porcelain insulated connectors.

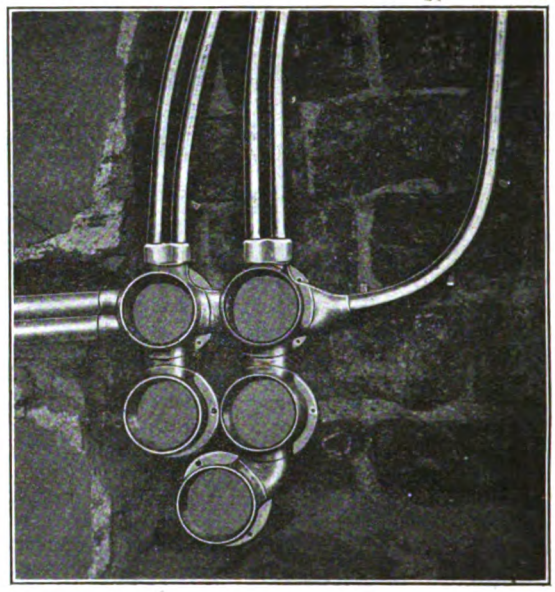

FIG. 7.—EXAMPLE OF CLOSE GROUPING OF SWITCH BOXES. The incoming leads enter by the two tubes on the left, are looped into the different switches and out again to the lights by the other five tubes.

In addition to the ordinary wiring system, circuits have been run for the Magneta clocks, which have been fitted in all the important rooms. Fifteen clocks have been installed, including the master clock, and these are principally of the open face wall type. In the secretary's office there is a magnetic timepiece on the fire mantel. The Sun Electrical Co. are the originators of the Kalkos system and manufacturers and suppliers of the tubes and fittings. They have supplied the whole of the Kalkos tubing and fittings for the new Institution building, and the actual erection has been carried out by Messrs. Drake & Gorham, Ltd.

Our thanks are due to Mr. P. H. Wigg, of Messrs. Drake & Gorham, Ltd., for his kind assistance in the preparation

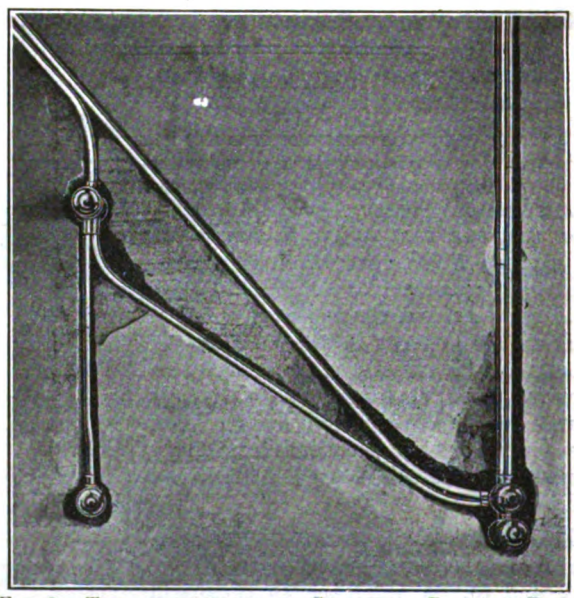

FIG. 8.—TYPICAL GROUPING OF SWITCH OR BRACKET BOXES. When the photograph was taken each box was temporarily sealed with a plasterer's cap.

of this article. The greatest credit is due to his firm, as contractors, for the very excellent manner in which the work has been carried out.

THE MECHANICAL MEASUREMENT OF THE WORK OF HYSTERESIS OF IRON IN A ROTATING FIELD.

BY G. VALLAURI.

Summary.—After reviewing the work of other investigators of this subject, the author gives his own results, which are in substantial agreement with those of previous observers. The angle of lag between the magnetising force and the intensity of magnetisation was also determined.

The dissipation of energy termed hysteresis which occurs in iron when subjected to a state of variable magnetisation has been chiefly studied for the case of an alternating magnetic field, the direction of which keeps constant. Although this occurs in practice, as, for example, in the case of the cores of static transformers, yet this simple condition does not always obtain, the direction of the magnetisation changing as well as its intensity. It becomes necessary, therefore, to obtain data of the loss which occurs in iron when subjected to a rotating magnetic field.

The existence of hysteresis in a rotating field ought to reveal itself by the presence of a couple tending to oppose the rotation of the field, or, what is equivalent, if we represent the intensity of magnetisation and the magnetising force by vectors **I** and **H** respectively, the vector **I** will lag behind the vector **H** by an angle of lag ϵ. The couple per unit of volume will be

$$\mathbf{H}\,\mathbf{I}\sin\epsilon,$$

and the work done per cycle becomes

$$w_r = \int_{\delta}^{2\pi} \mathbf{H}\,\mathbf{I}\sin\epsilon\, da.$$

For an isotropic material where **H** **I** and ϵ are constant, this reduces to

$$w_r = 2\pi \mathbf{H}\,\mathbf{I}\sin\epsilon.$$

The Molecular Hypothesis and Rotary Hysteresis.—It was at first considered an argument against Ewing's molecular theory of magnetism that rotary hysteresis vanished in fields of very great intensity. This, however, is not the case, and the molecular theory is really supported by the observation. Consider a body of iron subjected to an alternating magnetic field. During the period when the magnetising force passes through its zero value the molecules, which, by their grouping under the action of the magnetising force, produce the phenomena of magnetisation, have an opportunity of re-forming themselves into groups and chains. These groups are, however, broken up as the magnetising force increases again and a loss of energy occurs.

With rotating magnetising force, however, this is not the case, as the molecules are always under the action of this force, and have no opportunity for re-forming their arrangements. No energy will, therefore, be lost, and the direction of magnetisation will always coincide with that of magnetising force.

Previous Researches.—F. G. Baily measured the couple acting on a small bundle of iron or steel discs in a rotating field, calculating the eddy currents on the basis of a hypothetical distribution of the flux in the discs. The induction was carried up to a value of $\mathbf{B} = 20{,}000$. The same iron was also tested with alternating magnetisation. For rotating magnetisation the loss reached a maximum at $\mathbf{B} = 16{,}000$ and then rapidly decreased.

Grau and Hiecke tested a single disc in a manner similar to that of Baily, and found a maximum at $\mathbf{B} = 13{,}000$. They maintained from theoretical considerations that the maximum rotating hysteresis occurred for a value of $\mathbf{B} = 2/\pi$, the saturation value, and was equal to the maximum alternating hysteresis. For low inductions they considered that the rotating hysteresis should be twice the alternating.

Beattie and Clinker, also experimenting on a single disc hung by a torsion wire in a rotating field, found a maximum loss at $\mathbf{B} = 16{,}000$, falling to zero at $\mathbf{B} = 24{,}000$. Beattie also experimented on nickel and cobalt and obtained similar results to those with iron.

Martens revolved discs of iron in the earth's field, and measured the angle of lag ϵ, which he found to be greater the softer the iron.

Dina experimented on a ring made up of iron wire, causing it to rotate in the field of a dynamo and measuring the heating. He found the rotating hysteresis to be greater than the alternating for values of **B** up to 10,000 and less from 10,000 to 18,000, but the differences do not reach 10 per cent. These results are supported by tests made by Bloch.

Schenkel rotated iron discs in a fixed magnetic field and obtained a maximum loss at $\mathbf{B} = 16{,}000$, reducing to about 8 per cent. of the value at $\mathbf{B} = 23{,}000$.

Bauwens measured the angle of lag ϵ in a dynamo running idle by finding the position of the brushes for which there was no P.D. between them. He found increased as **B** was raised up to the value of 11,000.

Wecker, rotating metal rings in the interior of a solenoid, obtained values of the hysteresis greater than the alternating values, but never by more than 20 per cent.

Hermann, using a ring-shaped stamping wound with wire traversed by polyphase currents, and measuring the loss by means of a wattmeter, could detect no difference between the rotating and alternating hysteresis.

Weiss and Planer, using a rotating field created by powerful electromagnets in which was suspended a disc of soft iron, obtained values of the rotating hysteresis greater than the alternating hysteresis for values of **B** up to 15,000. The rotating hysteresis was a maximum at $\mathbf{B} = 16{,}000$, and diminished to zero at 21,500. Steel and nickel behaved similarly.

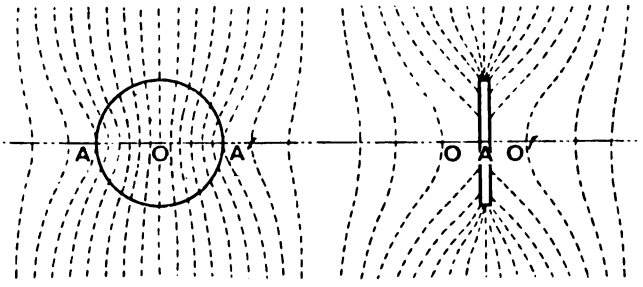

FIG. 1.

Vallauri carried out tests on an iron tube magnetised by two orthogonal fields, measuring the values of **I** and ϵ, and deducing the value of the rotating hysteresis $w_r = \int_{\delta}^{2\pi} \mathbf{H}\,\mathbf{I}\sin\epsilon\, da$. The rotating hysteresis was a maximum at $\mathbf{B} = 13{,}200$.

Summarising these results it will be seen that those of Bloch, Dina, Wecker and Hermann differ from those of the other experimenters, in that in their experiments the hysteresis measured is not in general a pure rotating hysteresis, but is a mixture of alternating and rotating and from the form and dimensions of the tests it will be seen that the first must in general prevail, so that the net result will not be far different from the case of a pure alternating hysteresis.

The other experiments give fairly concordant results, although to these measurements some objections may be made. They are somewhat handicapped in most cases by the smallness of the samples tested, which requires very delicate measurements of the couple

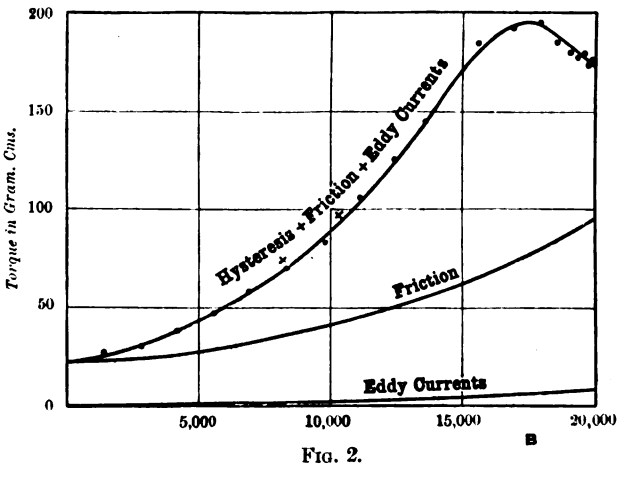

FIG. 2.

Revs. per min., 208.

and renders uncertain the measurements of the induction **B**. They also require high values of the velocity of rotation and consequently large losses due to eddy currents.

In practically all these experiments it is, moreover, doubtful whether the field in the specimen was uniform or whether it was not really of the shape shown in Fig. 1, in view of the distances between the test specimen and the polar extremities which were purposely made large in order to diminish the magnetic attractions.

The Author's Experiments.—In these tests a horse-shoe magnet of considerable size (area of cores 28·3 cm.²) was mounted on the end of the shaft of a 1·5 H.P. direct-current motor, and the magnet was fitted with suitably shaped pole-shoes formed so as to embrace a cylindrical space of 8·15 cm. diameter, in which was arranged the specimen consisting of a number of iron armature stampings of various diameters from 7·5 cm. to 8 cm. These discs had a thick-

Digitized by Google

ness of 0·332 mm. and were insulated from one another by paper. The total quantity of iron in the specimen was about 70 cc.

Owing to the magnetic attractions due to slight and unavoidable defects in the centring of the specimen, it was found necessary in the final tests to employ a diameter of specimen of only 7·6 cm. and to support the end of the shaft which carried these in a small bearing fixed to the magnet frame. This, of course, is open to the objection that it introduces a friction couple which has to be allowed for.

The couple acting on the specimen was balanced by means of a pair of adjustable weights sliding on a bar.

The flux passing through the specimen for different values of the magnetising current was measured ballistically by means of a coil of thin wire wound on a diameter of the specimen. This was used in conjunction with a ballistic galvanometer of long period of swing. Substantially the same values were obtained whether the magnet was rotated through 180 deg. or its exciting current was reversed.

It was also possible, by causing the search coil to assume successive angular positions, to investigate the distribution of flux in the gap so as to see whether the hysteresis was purely a rotating one. If this is to be so the distribution of flux density normal to the surface of the specimen must follow a sine curve. The form factors of three different measurements made by means of the search coil were 1·14, 1·14 and 1·13, as against 1·11 for the sinusoidal case.

It was further ascertained that even at velocities considerably greater than those actually employed the couple due to the movement of the air set up by the rotation of the magnet system was quite negligible, so that no error is anticipated on this score.

Measurements of the couple acting on the specimen were made for both directions of rotation and include in each set about 20 values

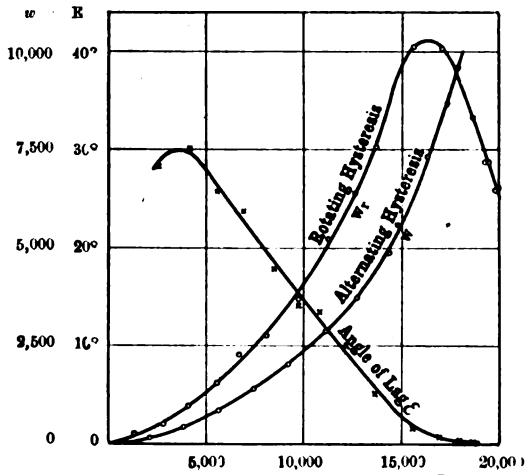

FIG. 3.

for inductions varying from a minimum of 1,300 to a maximum of 20,000. Between two measurements the current was cut off for a time so as to keep the temperature conditions constant. Although it was found that even after running for a quarter of an hour at 312 revs. per min. and B = 20,000, the heating of the bearing was scarcely sensible and the specimen was quite cool. Before taking a reading the current was reversed several times and measurements taken with increasing or decreasing currents were found to present no systematic differences.

Measurements were taken at speeds of 104, 208 and 312 revs. per min., and the mean values given refer to a speed of 208 revs. per min. Notwithstanding the presence of friction and eddy current effects the curve shows a well-marked maximum corresponding to the point of maximum hysteresis.

Separation of Effects of Hysteresis and Friction from Total Couple.—The separation of the eddy current losses was accomplished by taking measurements at the three speeds given. Subtracting the couple exerted at 104 revs. per min. from that at 312 revs. per min., and assuming the proportionality of the eddy current loss to the square of the frequency, the mean couple at 208 revs. per min. due to eddy currents only was obtained. From this was deduced the value of the coefficient β which had to be inserted in the equation

$$w = 2\beta\delta^2 n^2 B^2,$$

where w is the loss, δ the thickness of the laminations and n the frequency, the factor 2 being introduced to take account of the fact that eddy current loss is twice as great for a revolving flux as for an alternating one.

This gave a value of $\beta = 0{\cdot}000228$, which agrees well with Epstein's figure of 0·000224. Using this figure the curve of eddy current torque given in Fig. 2 has been drawn.

The torque due to friction has been separated by means of tests made on the starting friction with the magnet system stationary. This was observed with various values of the flux density. The running friction was also measured with the field magnet revolving but deenergised. The starting friction was thus found to be equal to 1·52 times the running value, and it is assumed that this relation holds good right throughout the series.

The friction was found to follow a relation of the form $y = a + bB^2$, which is to be expected, as the load on the bearing was made up of two parts, viz., the weight of the specimen and the force due to defective centring in the magnetic field. Knowing the values of both the eddy current and friction torques, that due to hysteresis is found by subtraction.

From the results has been drawn the curve in Fig. 3, which gives the hysteresis loss at different values of the flux density B, and which shows a well-marked maximum value of 10,400 ergs for B = 16,000, falling to 6,300 for B = 20,000.

Comparison with Alternating Hysteresis.—Tests were made on 60 rings 11 cm. × 8 cm. diameter, punched out of the same sheet as the specimens, wound with wire and tested ballistically in the ordinary way. The relation w_r'/w_a', which for low values of B is equal to or slightly over 2, becomes unity at B = 17,800 and steadily decreases towards zero.

The Angle of Lag.—For the expression given earlier in the Paper, viz.—

$$w_r' = 2\pi H I \sin\epsilon,$$

we may without any serious error write

$$w_r = \tfrac{1}{2} H B \sin\epsilon,$$

and from the values of w_r obtained from the tests ϵ may be calculated. It is found to have a maximum value at about B = 4,000, and tends to a zero value at saturation.

The angle of lag was also observed experimentally by placing a search coil on a diameter of the specimen and arranging a contact breaker to connect the terminals of the coil to a ballistic galvanometer at a definite point in every revolution of the magnet. The contact maker having been adjusted for a maximum deflection the direction of rotation was reversed, and the angle through which the search coil had to be revolved to give again a maximum was equal to twice the angle of lag ϵ. This, again, gave a maximum at about B = 4,000.

ASSOCIATION OF CONSULTING ENGINEERS.

On Wednesday of last week, a meeting, presided over by Sir William Preece, K.C.B., F.R.S., was held at Caxton Hall to consider the desirability of forming an Association of Consulting Engineers, the object of the Association being to improve the status of the profession and to place it on a more satisfactory basis than hitherto.

Invitations had been issued to a number of consulting engineers, at the instance of a Provisional Committee, and the invitation was signed on behalf of this Committee by the following members:—

Representing Civil Engineering: Messrs. W. T. Douglass, E. L. Mansergh, Midgley Taylor and Henry Rofe.

Representing Electrical and Mechanical Engineering: Messrs. B. M. Jenkin, W. M. Mordey, Llewellyn Preece and James Swinburne.

Representing Gas Engineers: Messrs. C. G. Hunt and E. H. Stevenson.

Mr. A. H. Dykes, as hon. secretary of the Provisional Committee, read letters of regret at their inability to attend the meeting from Messrs. Charles Bright, E. M. Lacey, C. Hunt, H. Humphreys, W. H. Patchell, C. P. Sparks, W. T. Douglass, H. Rofe and J. F. C. Snell, all of whom expressed themselves as being heartily in sympathy with the objects of the meeting.

Mr. MIDGLEY TAYLOR, who presided at the opening of the meeting pending the arrival of Sir William Preece, who was detained, said that the object of calling the meeting was to form an Association of Consulting Engineers. The subject had been before several consulting engineers for the past two years, or more, and as some initial step had to be taken, the members who originally took the subject up formed themselves into a Provisional Committee and had held a large number of meetings, with the result that the present meeting had been called to confirm, or otherwise, the action taken by the Committee in the past. The object of the meeting was to see whether the general idea of the formation of the Association met with the approval of consulting engineers in this country. Everyone knew that quite recently the Institution of Civil Engineers had helped the consulting engineer to the best of their ability by form-

Digitized by Google

ing rules for professional conduct, and he was sure that every engineer would feel that that was a step in the right direction. He had no doubt that from the point of view of the Council of the Institution of Civil Engineers they (the Council) had gone as far as that body could go. He thought the membership of the Institution was something approaching 10,000; probably the regular consulting engineers in this country were not 5 per cent. of that body, and therefore the self-appointed Committee considered that the Council of the Institution could not, in the very nature of things, give all the protection that was desirable for the consulting engineer. He wished to emphasise the point that the Committee had not been working in any antagonism to the Institution of Civil Engineers, but had been endeavouring to go one better than was possible for that body. He felt that the public wanted protecting. At the present time, if municipal authorities erected works, even of large magnitude, they were not compelled to employ a qualified man to advise them, and there was nothing to prevent an absolutely unqualified man going to the particular authority, touting for the work and being employed. Under those circumstances he felt they should endeavour to form an Association such as would not only protect themselves, but would also protect the various public bodies and persons in this country who were anxious to get a properly qualified man to advise them on engineering works. He felt that those unqualified men who endeavoured to take the work out of one's hands, even after the appointment had been made, should not have the standing that would belong to the members of a body such as it was proposed to form. The Committee hoped that the meeting would result in the formation of the Association, but at the same time they wanted to have an open expression of opinion from everyone, whether they were favourable or otherwise. He then called upon Mr. James Swinburne (who had interested himself in the movement from the very beginning) to propose the formation of the Association.

Mr. JAMES SWINBURNE formally proposed that the Association be formed at once, but he first wished to say that the self appointed Committee had met with many difficulties. First, there was an idea that there was some antagonism between the proposed Association of Consulting Engineers and the Institution of Civil Engineers and other institutions. The only thing that a body like the Civil Engineers could do was to frame rules of etiquette which were very good things in themselves, but which really limited the powers of the genuine consulting engineer rather than helped him. It was, therefore, necessary that consulting engineers should work in sympathy with the Institution of Civil Engineers and other institutions, and that they should, in addition, form an association themselves, not for the purpose of technical papers but purely to guard the interests of consulting engineers as such, and of the public in so far as the latter were bound up with the interests of the consulting engineer. The great difficulty in forming an association was that people were apt to split over small differences of opinion. He therefore asked the meeting to look at the matter as broadly as possible, and not to consider whether any particular rule interfered with their own ideas. He also urged the older members of the consulting profession not to stand aloof because they were in a position sufficiently independent not to be affected by the malpractices of those who were not genuine consulting engineers. By lending their names to the movement they would be helping the younger consultant, who was the man to be looked after. As to the rules that had been circulated, the idea was not to adopt them immediately. All they could do was to say whether they were going to have an Association of Consulting Engineers or not. If they were, then they had to appoint something—a temporary committee or something of that sort—to which the details of formation and rules of the Association could be handed over for consideration to be finally approved by the members of the Association. In the case of this first meeting it was obviously impossible to make the list of invitations as complete as the Committee would desire. It was hoped that any who had not yet been communicated with, would understand that the Association was intended to cover the broadest possible field consistent with its objects, and that those corporate members of the Institution of Civil Engineers who were practising purely as consulting engineers, would, by sending in their names, assist the Secretary in compiling his list of membership for submission to the Committee.

The motion having been seconded by Mr. E. L. Mansergh, a general discussion took place.

Mr. E. H. STEVENSON remarked that he only wished such an Association had been started 20 or 30 years ago, and although it might not now affect the older members like himself, it would be of very great assistance to the younger consulting engineers. Mr. Robert Hammond dwelt upon the importance of such an Association from the public point of view. Although a private company was quite at liberty to have work carried out in any way that might seem desirable, in the case of municipal work it became highly desirable that public money should be spent only under the guidance of properly qualified engineers. A good deal of the discussion turned upon the question of the name of the Association. Thus, Mr. A. H. Preece, whilst expressing on behalf of his firm entire accord with the step that had been taken, thought that a committee might be sufficient without any formal Association. On the other hand Mr. Swinburne, Mr. Midgley Taylor, Mr. Lowcock, Mr. Hammond and others, were strongly in favour of an Association with a Council, owing to the fact that such a body would carry more weight with Government officials, Courts of Law and the general public. Mr. W. M. Mordey saw no objection to the formation of an Association from the point of view of adding to the already long list of societies, because its functions would be very different from those of the ordinary society. He was of opinion that a great deal depended upon the selection of a suitable name, and he thought it would be best to call the society an Association.

There was also some discussion as to whether the term "consulting engineer" was altogether the best to be adopted in the name of the Association. Mr. Druitt Halpin thought it was undesirable, but other speakers thought it was difficult to substitute any other term. Mr. A. P. I. Cotterell asked whether the Institution of Civil Engineers were in favour of the scheme, as otherwise the Association might come in conflict with the Institution sooner or later, which would be highly undesirable. In reply to this question Mr. A. H. Dykes said that he had received a letter of a most sympathetic nature from the Secretary of the Institution of Civil Engineers.

The formation of the Association was also supported briefly by Mr. Campbell Swinton, Mr. B. M. Jenkin and Mr. H. W. Handcock.

Sir WILLIAM PREECE, who had arrived during the discussion and had taken the chair, said he was entirely in sympathy with the movement. Most of the discussion had been on the question of the name which was not very important at the moment. He assured them of the sympathy of the Institution of Civil Engineers, and he was sure that the Committee of the Association would be received heartily by the Council in the discussion of any points that might arise. What they wanted was to band themselves together as brothers in a similar profession with a very strong committee and strong chairman. He then put the resolution, that the Association be formed, to the meeting, and declared it to be carried unanimously.

The Chairman then read the list of names of the suggested Committee, the names being as follows:—

As representing *Civil Engineering:* Baldwin Latham, S. R. Lowcock, E. L. Mansergh, Henry Rofe and Midgley Taylor.

Electrical and Mechanical Engineering: Messrs. Robert Hammond, B. M. Jenkin, W. M. Mordey, W. H. Patchell, Sir Wm. Preece, J. F. C. Snell, James Swinburne.

Gas Engineering: Messrs. C. Hunt, E. H. Stevenson and Henry Woodall.

No further names being forthcoming, the Committee were elected as above, with power to add to their number, to take what steps they considered desirable for the formation of the Association, and to formulate rules to be submitted to a general meeting to be called in the autumn.

Mr. B. M. JENKIN explained the lines on which a code of rules had been drawn up by the Provisional Committee, and placed them formally at the disposal of the new Committee. The Committee drew up a set of rules which they handed to the Institution of Civil Engineers for consideration. There was a proposal at that time that the Institution might distinguish in their list of members between those acting as consultants and others, but the Council were not prepared to do so. The object of the rules was to define what a consulting engineer was, and one of the objects of the Association was to make all consultants join together and work together along definite professional lines. That was extremely difficult, as one could only define a consulting engineer by saying what he could or could not do, but it was hoped that the rules would define pretty clearly what he might or might not do, and would be a help to young consultants as to what their professional conduct should be, and teach the public what a consulting engineer is. The idea was to print the rules with a list of members, so that anyone who wished to obtain a consulting engineer could consult the register. The rules were not complete, or in their final form, but were issued primarily with a view to discussion later.

Mr. JAMES SWINBURNE proposed the election of Mr. A. H. Dykes as honorary secretary, reminding the meeting that the success of the matter was entirely due to him, and this was seconded and carried unanimously.

Mr. DYKES responded briefly in accepting the position, and the meeting terminated with a vote of thanks to Sir Wm. Preece for presiding.

Amongst those who accepted the invitation to the meeting or who wrote that, whilst unable to be present, they were in sympathy with the movement, were: J. S. Alford (Messrs. Chatterton & Alford), Walter Beer, W. I. E. Binnie (Messrs. Sir Alexander Binnie, Son & Deacon), Charles Bright, F. Broadbent (Messrs. Wilkinson & Broadbent), H. R. J. Burstall, H. R. Carr, A. P. I. Cotterell, A. T. Coode (Messrs. Coode, Son & Matthews), W. R. Cooper, Martin Deacon, A. L. Dearlove (Messrs. Clark, Forde & Taylor), R. A. Dawbarn, W. T. Douglass, A. H. Dykes, S. Moore-Ede, Tom Ekin, Percy Griffith, Robert Hammond, Robert Hammond, jun., H. W. Handcock, K. P. Hawksley (Messrs. T. & C. Hawksley), G. W. S. Hawes, H. M. Hobart, H. H. Humphreys, C. Hunt, F. H. Jones, B. M. Jenkin and J. M. Kennedy (Messrs. Kennedy & Jenkin), Baldwin Latham, E. M. Lacey, S. R. Lowcock, E. L. Mansergh and W. L. Mansergh, John May, J. C. Mellis, C. H. Merz (Messrs. Merz & McLellan), E. W. Monkhouse, William M. Mordey, W. H. Patchell, A. F. Phillips, Sir William Preece, A. H. Preece, Llewellyn Preece, Henry Rofe, Henry Rofe, jun., A. M. Sillar, A. T. Snell, J. F. C. Snell, E. J. Silcock, C. P. Sparks, E. H. Stevenson, James Swinburne, A. A. C. Swinton, Midgley Taylor (Messrs. Taylor, Son & Santo Crimp), W. C. Unwin, Robert Weekes, Henry Woodall (Messrs. Corbet Woodall & Son), A. Valon, G. A. Yourdi.

The honorary secretary of the Association is Mr. A. H. Dykes, of 1, Victoria-street, Westminster, S.W.

STANDARDISATION OF FUSES.

We give below an account of the discussion that took place at the meeting of the Birmingham local section of the Institution of Electrical Engineers when Mr. H. W. Kefford read his Paper on the above subject. An abstract of this Paper appeared in our issue of May 27th.

Mr. J. F. Crowley thought it was desirable that fuses should be so standardised that it was impossible for one of the wrong capacity to be put in circuit. He took exception to one point in the Paper. The author, in treating of the minimum limiting current of a fuse, had referred to four hours as a practical time to allow. He thought that this should be increased to six hours or even more. He would also like a better definition of the short-circuit test. The capacity of the circuit and also its inductance must be taken into account. Possibly one reason for the somewhat chaotic state of the fuse question was that cut-outs were extensively used instead of fuses. For small currents he thought that fuses were the correct thing.

Mr. A. E. Gott took objection to the statement in the Paper that fuse selection was decided on considerations of ornamentation. There was no doubt, he thought, that they were getting nearer and nearer to the solution of a perfect fuse, but they had not reached finality yet. The overloads allowed by the author on his fuses before they blew seemed rather too small. A fuse should not be expected to save plants from overloads which if continued would injure them; its proper function was to save them from destruction under abnormal conditions. Where small margins of operation were required, the right thing was to use circuit-breakers, which could be set for any desired overload or time limit. These were more reliable and dissipated less power. Short fuses under certain conditions of the circuit failed to cut off the current, and so supply authorities had insisted on definite lengths for certain currents and voltages. The P.D. loss over such a fuse was the price of real safety. The economical fuse of the future would probably be a fraction of an inch in length, but with a mechanical means for increasing the gap at the moment of fusion. Nothing had been said in the Paper about the porcelain which formed the body of the fuse. As a general rule this was of bad quality, and it would probably pay manufacturers to go to some trouble to get a suitable variety for the purpose. The author had stated that the limiting current was a perfectly definite quantity but the speaker disagreed with that, because the effects of a draught had not been taken into account. With some types of fuses the opening of a door would considerably affect the limiting current.

Mr. Lindsay Foster said that he had found the use of asbestos-covered wire for fuses made the explosion when a fuse blew much less violent. As to regulations for the interchangeability of fuses, these would be of great value; but the day for them had not as yet arrived.

Dr. Kloss referred to the question of the supply company fixing a definite minimum length between the poles of a fuse. This was all very well with the old type of fuse, which when it blew produced an arc, but it was not right that such restrictions should be made to apply to fuses in which there was no arc produced. He would like to take the opportunity of pointing out again how important it was in drafting specifications not to stick to certain words which had been in use in past times, but always to specify what was required—the object and not the means. If the object only were specified, the designer was left freedom to develop new ideas.

Mr. Shaw asked up to what size the fuses were made so that they could not be tampered with by an incompetent man. With larger currents it was generally the case that the man in attendance was not incompetent.

Mr. A. M. Taylor thought that in the case of a fuse connected to 'bus bars, with a large amount of power behind, the rush of current was far greater than indicated by the instruments. He had made some rough calculations of the rate at which the temperature of a fuse would rise on short-circuit with definite currents flowing, and he had come to the conclusion that it was not possible for a fuse to blow in the short interval of time frequently observed, unless the rush of current was very great indeed. This, he believed, was the reason for some of the alarming things which Mr. Kefford had shown in the photographs.

The Chairman (Mr. R. K. Morcom) remarked that, once things became standardised, one got authorities laying down limits, and they generally laid them down as inconveniently as possible. He believed that any standardising of fuses would lead to even more tampering with circuits than at present.

Dr. D. K. Morris, in a written communication, said that the author gave at the end of his Paper a suggested basis for a specification for standard fuses. As a device for opening a circuit on overload through the heating effect of such overloads, the fuse had until recently been the only apparatus available. It was interesting, however, to notice the remarkable way in which the thermally operated time element circuit-breaker now met all the requirements of the author's specification. In addition, the circuit was always ready for immediate closing without the delay in replacing and re-wiring a fuse.

Mr. Kefford, in reply, thought that Mr. Taylor had arrived at such remarkable results owing to his having neglected to take into account the rise in resistance of the copper with the temperature, which would greatly decrease the time taken to blow the fuse and bring the results of calculation and observation into line. As for the question of standardisation, if the time had not then arrived he really did not know when it would. With regard to Mr. Shaw's inquiry, the gauge rings could be easily altered if one had the key. To the ordinary user there was, however, nothing to show that it was not a part of the fitting. Competent mechanics would, no doubt, find all sorts of dodges for changing it, but would have to answer for it afterwards.

ACTINIFEROUS RADIO-ACTIVE EARTHS.

[Communicated.]

The researches in the laboratory of M. and Mdme. Curie at Paris, which led to the discovery of radium and polonium, have had several other interesting results, scientific and practical. Amongst the latter are the so-called actiniferous earths of permanent activity, which have been the subject of prolonged clinical experiments by the French pathologists. These "earths" are constituted from the bye-products of the process involved in the separation and extraction of uranium, and form the residue of the ores used for that purpose, their activity being due to that remarkable element actinium, discovered by Becquerel, of which so little is known. It has been known for some time that the curative effects of the "mud baths" of Bohemia are due to their radio-active properties, although prior to the discovery of radium and radio-activity the cause was unknown, or ascribed to chemical agency. Unfortunately, the potency of these earths or muds disappears when they are exported, and this was ascribed to some obscure change in their chemical constitution, by which the volatile beneficient elements in them became dissipated. Now, however, it is known that the existence of the radio-active emanations which give these earths their pathological value is limited to a definite period, and, therefore, the earths must be used when fairly fresh, *in situ*, or, in other words, during the life of the emanations.

The actiniferous earths, the residue of the uranium extraction, are, however, not subject to these objections; not only have the French pathologists shown that they may be utilised with success for all purposes where natural mud baths are employed, but for other cases and with more varied application; and, lastly, they can be transported without loss of their radio-active properties—indeed, their radio-activity is permanent. This apparent paradox is due, firstly, to the misuse of the word "radio-active," which term, originally applied by Becquerel to the activity of certain elements, has since been associated more largely with radium and its action of dissipating its atomic energy, which is, however, not strictly permanent; and, secondly, to the fact that these residues owe their so-called radio-activity principally to quite another element, namely, actinium. The ores from which uranium is extracted are, in contradistinction to the source of radium, minerals other than pitch-blende, and others not containing silicates. On analysis, the residues are found to consist of oxide of iron, alumina, phosphoric acid combined with iron and aluminium, oxide of uranium, oxide of manganese, carbonates and sulphates of sodium, oxide of silicon, sulphate of lead, carbonate of calcium, and, finally, the "radio-active" elements actinium, polonium and radium. The last is, however, present in such small traces that it is quite negligible, whilst polonium disintegrates so rapidly that its effect may also be considered nil. But the new element actinium, to the life of which no period has at present been set, is the radio-active factor of

Digitized by Google

importance in these residues, or earths, which owe practically all their activity to its presence, and have, therefore, been named "actiniferous."

The comparison of the radio-activity of actinium and radium is interesting. The French method is to take the spherical activity of uranium as the standard, and with this equal to unity, it is calculated that the approximate activities of radium and actinium are 2,000,000 and 20,000,000 respectively, whilst that of the actiniferous earths is 0·15, and from this it is estimated that the earths contain $\frac{1}{3000000}$th of their weight of actinium.

Radium, as is well known, gives off three kinds of "rays," which have been called the *alpha*, *beta* and *gamma* rays. The *alpha* rays are small particles shot off at a very high velocity, which find a difficulty in penetrating metals, except very thin aluminium and natural organic substances. The *beta* rays are particles about one thousand times as small as the *alpha* rays, having a velocity from three to 10 times as great, and are capable of penetrating metals more easily. The *gamma* rays are vibratory, similar to X-rays, and are still more penetrative. Actinium gives off three kinds of rays like radium, and these, for purposes of convenience, have been called *alpha*, *beta* and *gamma*; the first two are corpuscular, and the third vibratory, but, so far as is known, the resemblance is a relative one only. It has been found possible, however, to arrange a table of the breaking down of actinium, which shows an interesting similarity to that of the radium group.

	Half life.		Radiation.
Actinium	?	.....	inactive.
Radio-actinium	19·5 days	.....	alpha
Actinium X	10·2 „	.....	„
Emanations	3·9 weeks	.....	„
Actinium A	36 months	.....	beta
Actinium B	2·15 „	.....	alpha
Actinium C	5·1 „	.....	beta, gamma

This table shows that actinium differs from radium in two important respects, namely, that the *alpha* rays are given off in large quantities, whilst the *beta* rays are quite uniform, whereas in radium they are divided into *beta* soft, *beta* medium and *beta* hard.

The actiniferous earths present several other points of interest besides those of the purely physical aspect, in which there is a large field for investigation, and these may be referred to briefly. For instance, on the biological side, whilst their *alpha* and *beta* rays are known to affect adversely vital organisms when applied in large doses locally, if the dosage is spread over a large area the harmful effect is said to be eliminated. The emanation, also, may be employed for prolonged effects to any vital organism without any apparent injurious action. On the therapeutical side there is much to be said. The presence of the emanation permits of *a priori* investigations along the same lines as those employed for the applications of mud baths, with more successful results in view on account of the actiniferous origin of the emanation, its constancy, the coexistence therewith of *alpha*, *beta* and *gamma* rays, the large proportion of the *alpha* rays, and finally, the fact that these earths are 50 times more radio-active than the natural earths, or mud baths. Further, in comparison with the applications of radium salts, the actiniferous earths present several advantages. The former, although they have much larger spherical activities (varying from 500,000 downwards according to the form of applicator or screen employed) are confined to a more or less limited part of the body. The earths, however, being applied in the form of a soft paste, may be spread over as large a surface as desired for direct application, or they may be suspended in water and the patient can be subjected to a radio-active bath. Now, whilst the activity is only 0·15, which implies that a centigramme spread over a square centimetre has a spherical radiation of 0·15, if this figure be multiplied by the area of the surface over which the earths are spread (and more than a centigramme may be applied per unit area), it is possible to obtain a much stronger dosage of radiation than with a radium applicator, although the specific activity is so much weaker. In consequence of the local action being mild, the applications may be prolonged—in fact, from several hours to several days, without (it is claimed) harmful results. It has been shown by experiments of the French doctors that the actiniferous earths have no antiseptic action which might tend to neutralise their vital effects on the tissues, nor do they act like a caustic or a poison. In fact, although microbes are not killed in their presence, the stimulating action they set up tends to dissipate infection. It is hardly within the province of this article to deal with the pathological aspect of these new earths, but reference may be made to the researches in Paris, which have shown excellent results in the treatment of rheumatism, neuritis, gout, eczema, rheumatoid arthritis, gonacoccal rheumatism, &c. It is, of course, well known that vibratory massage will stimulate the muscles to resume their normal healthy state in diseases of this description, and it would almost seem as if the mild, but prolonged bombardment of the cellular tissue by the corpuscles thrown off from the actinium, produced a whipping or vibratory effect of an extremely beneficient nature. The earths are applied by coating the affected parts with a layer, sterilised if necessary, and covering this with oiled silk to preserve the moisture and thus to ensure the production of emanations. If the earths become too dry they may be moistened with water, and they can be used over and over again because the activity is permanent. The duration and frequency of the applications depend, of course, on the nature of the case. Another method of application is by baths. This is necessary when the indication is general rather than local. About 250 grammes of earth are usually used for a bath of about 50 gallons, the temperature being 37°C. and the application half an hour. If necessary, a local bath may be employed or even injections.

The study and applications of actiniferous earths are, however, only in their infancy. But sufficient has been done abroad, as shown by this brief record, to indicate that they have valuable scientific and therapeutical properties; and the investigation of actinium, having a radio-activity 10 times as great as radium, with the parallel researches in regard to its effect on the diseases of the human organism, will be watched with interest and sympathy.

MAGNETIC DISTURBANCES AT KEW.*

BY C. CHREE, SC.D., F.R.S.

A recent Paper† discussed the diurnal inequality of Kew magnetic declination derived from 209 of the most highly disturbed days of the 11 years 1890 to 1900. The present Paper discusses the corresponding phenomena for the same days in the other magnetic elements. The most prominent features of disturbed days are the irregular nature of magnetic changes and the frequency of large oscillations. These more obvious features have hitherto engrossed attention. It is found, however, that the irregular changes on disturbed days are accompanied by large regular diurnal changes, which are specially striking in vertical force. In declination and horizontal force the range of the regular diurnal inequality on disturbed days is in the average month of the year about double that on quiet days, but in vertical force the former range is fully four times the latter. Disturbance affects the type as well as the range of the diurnal inequality. The former influence is comparatively small in horizontal force and the component to geographical north, larger in declination and the component to geographical west, and largest of all in vertical force. On quiet days the characteristic feature of the vertical force inequality is the fall in the forenoon to the minimum about 11 a.m. and the rapid rise in the early afternoon. Disturbed days, however, approach to a type in which there is a minimum about 4 a.m.—near the principal barometric minimum for the day—and a maximum at from 4 p.m. to 6 p.m., according to the season. The day rise and the night fall are about equally rapid. On disturbed days the shorter period Fourier "waves" in the diurnal inequality for V become of reduced importance relative to the 24-hour wave, and this wave has its phase some four hours earlier than on quiet days. Vertical force inequalities from the disturbed days of the four sunspot maximum years, 1892–1895, show a considerably larger range than those from the whole 209 days, and their phase angles depart more from the phase angles for the quiet days of the 11 years.

The question of the seat of the forces to which the regular diurnal inequality is due turns largely on the vertical force phenomena, and it is thus clear that different results may be reached according to the extent to which the disturbance element enters into the data employed. Dr. Schuster, employing results from 1870, a year of exceptionally large sunspot frequency, and Dr. Fritsche, employing data from miscellaneous years, have reached notably different conclusions. The results of the present Paper emphasise the importance of securing as great uniformity as possible in the data from different stations. It is suggested that three sets of diurnal inequalities might be published, representing respectively quiet days, highly disturbed days and intermediate days. If the diurnal inequality is due, as Dr. Schuster concludes, to electric currents associated with the movements of the upper atmosphere, the increased conductivity of these regions due to increased ionisation may account for the increased amplitude of the regular diurnal inequality at sunspot maximum, or on days of magnetic disturbance. But it is not obvious how it can account for large differences in phase angles between quiet and disturbed days, or for the difference that manifests itself in the effects of

Digitized by Google

disturbance on different magnetic elements. It is possible that the variation with altitude in the electric conductivity of the air is altered, so that appreciable effects are experienced on disturbed days from electric currents in layers which are normally ineffective. Thus differences between the upper air movements at different heights might make their presence felt.

If magnetic storms were of approximately constant length—under 24 hours—and followed on the whole a similar course, then the existence of a regular diurnal inequality on disturbed days might mean that storms commenced more often at one hour of the day than another, and not that the forces modifying the nature of the phenomena were largely dependent on local time. Influences of this kind do not improbably have some effect. The time, however, during which magnetic conditions remain highly disturbed is very variable. Of the 209 days included in the Paper only 64 were days of isolated disturbance; the remaining 145 were all preceded or succeeded by days also classified as disturbed. There are several other reasons for concluding that the diurnal inequalities discussed in the Paper indicate in the main a true daily variation, independent of the stage that the magnetic disturbance has reached. An inspection of individual vertical force disturbances of short period showed that when these occurred in the late afternoon there was almost invariably a rise in the force, whereas if they occurred in the early morning there was a fall.

It was found, however, that the non-cyclic changes experienced on disturbed days did depend in a marked way on the stage reached by the disturbance. When a disturbance lasts for two days, or more, the usual phenomenon is for westerly declination, horizontal force and vertical force to fall during the first day and rise during the second. The fall on the first day predominates in the case of the horizontal force, the rise on the second day in the case of the vertical force.

In ion-emission theories of magnetic storms—such as that of Prof. Kr. Birkeland—the question of the height and extent of the hypothetical electric discharge turns largely on the vertical force phenomena. The fact that so large a proportion of the vertical force range during magnetic storms proves to represent a regular diurnal inequality seems not unlikely to prove a crucial test for such theories.

SOME NOTES ON A TRIP TO THE NORTH AMERICAN CONTINENT.*

BY MAJOR W. A. J. O'MEARA, C.M.G.

Summary.—The author gives an account of the various telephone and telegraph installations visited by him on his recent trip to the United States. Useful comparisons are drawn between American and English practice, especially as regards the commercial and engineering organisation.

The success of the American in engineering and commercial enterprises is widely acknowledged, and I therefore endeavoured to ascertain during my hurried journey through the United States and Canada to what this success could be fairly ascribed. I have no hesitation in stating that from September 16th, the day I investigated the organisation of the New England Telephone Co. in Boston, and the methods adopted by its officers in handling telephone propositions, to December 21st, that last day which I spent at the offices of the American Telephone & Telegraph Co. in New York with Mr. J. J. Carty, I was struck by nothing more than the broad-mindedness of the officials engaged in the telephone and telegraph industries of the New World, and the orderliness in the management of those undertakings behind the scenes of which I was, through generosity and kindliness, allowed to penetrate.

At the time that the first rudimentary telephone exchange was established in Boston, in the year 1877, the original telephone patents were acquired by the American Bell Telephone Co. This company, now known as the American Telephone & Telegraph Co., was in consequence put into a position to control the telephone situation throughout the United States, and has done so most successfully. At one time and another some 43 so-called Bell companies have been incorporated under separate boards of directors, and have carried on local service telephone exchanges under licence from the parent company; these licensee companies have at the same time provided the "short haul" trunk lines. The so-called "long distance" service, that is to say, the lines connecting the systems of the associated operating companies with one another, is owned and operated by the American Telephone & Telegraph Co., and in consequence the trunk line service as known to us is partly owned by the licensee companies and partly by the parent company. The American Telephone & Telegraph Co. also holds stock in the Western Electric Co., and exercises a very complete control over the policy of this concern. In consequence, the American Telephone & Telegraph Co. is further able to maintain its lead in the van of telephone progress by keeping closely in touch with the latest developments in the field of invention.

On the North American continent the telephone and telegraph systems are ranked among the engineering enterprises of the land, and it is therefore not surprising to find the prominent position which is accorded to the engineering department in the organisation of the American Telephone & Telegraph Co. In the words of Mr. Theodore Vail, the president of this company: "The engineering department takes all new ideas, suggestions and inventions, and studies, develops and passes comments upon them. It has under continuous observation and study all traffic methods and troubles, improving or remedying them. It studies all construction, future development and extension schemes, makes plans and specifications for the same, and gives, when desired, general supervision and advice."

Whilst I was in New York I had many opportunities of closely watching the working of the great deliberative machine so ably presided over by Mr. T. Vail, and so well managed by Mr. H. B. Thayer, one of the vice-presidents of the company. The first thing which naturally attracted attention was the complete absence of the huge files of correspondence so familiar to those who work in Government offices. The functions of the various departments of the American Telephone & Telegraph Co. are very clearly laid down, and since decentralisation exists in its completest form, the business of the company is transacted by the heads of departments in personal interviews with the president and vice-president. It is this procedure which accounts for the absence of the files of correspondence to which attention has been drawn, and to it is also due the fact that the staff attached to the offices of the president and vice-president are reduced to microscopical proportions. In the case of the American Telephone & Telegraph Co. I understand that about half a dozen stenographers comprise the whole of what would constitute the administrative section in a large British public department. Another point which came under my observation was the close personal relationship which exists between Mr. Carty and the chief engineer of the Western Electric Co., Mr. C. Scribner. When one considers the character of the problems which telephone and telegraph engineers have to handle nowadays it is not difficult to realise how great must be the advantages which cannot fail to result from the close personal intercourse of the chief engineers of the manufacturing and operating departments of the American Telephone & Telegraph Co.

Mr. Carty's mission is to provide for the handling of telephone traffic in an efficient manner, it naturally follows that one important sub-division of his department devotes itself to the study of traffic questions. A second sub-division deals with questions relating to equipment, &c., by means of which the traffic must be handled. The work of these two sub-divisions is closely associated, as the problems of the one interact on those of the other. In order to produce the highest efficiency with the greatest possible economy it is absolutely necessary to consider the traffic problems in relation to the design of equipment and vice versa. Mr. Carty put it well when he informed me that his responsibilities "covered the design of the guns and ammunition, and also the manner in which the ammunition was to be used and the guns fired." But he further impressed upon me the fact that his responsibilities did not end here. For, if a telephone undertaking is to be a commercial success, it is a further duty of the engineer to follow carefully every change in the commercial policy of the company with which he is associated, since matters relating to tariffs, concessions, &c., all in turn produce reactions both on the internal equipment and external plant, and such reactions often demand important modifications in the engineering plant to meet the altered traffic requirements arising from a change in policy.

In America a commercial department has been instituted for selling telephone service. Secondly, in order to enable the telephone companies to fulfil their part of the contract after the bargain for the service has been entered into, the necessary equipment and plant have to be designed, installed and maintained; the responsibility for this work is provided for by the plant department—*i.e.*, the engineering department as known in our service. Finally, when the equipment and plant are in position it necessarily follows that measures have to be adopted for bringing them into service, and the responsibility for this work is placed upon the traffic department. A feature of this organisation which struck me as admirable lies in the fact that the heads of these three departments have the same title, viz., that of superintendent—that is to say, they are on the same level as to rank, and thus human sentiment is very largely cared for. It is safe to say that with such an organisation business getting will be

* Abstract of an article in the "Post Office Electrical Engineers' Journal."

Digitized by Google

much more effectively organised and carried on; the equipment and plant will be better designed and constructed, and maintained at lower cost, and the operating will be of higher quality and exhibit greater efficiency. The concentration of effort, the conserving of special skill, the co-ordination and co-operation within each functional department, will also tend naturally to the acquisition of the greatest efficiency in each department of work.

In my young days it was frequently impressed upon me that the best results would always follow if subordinates, however lowly in rank, were given an opportunity to do at least one thing on their own responsibility. This idea has been made a principal feature in the functional organisation in the form in which it has been introduced in America. I found that every effort is made to push responsibility down the line, and hence it is that in every grade officials know that there are always certain things in which no further authority than their own judgment is required for the execution of prescribed works. I could not help noticing the spirit of enthusiasm which is thus engendered, and I readily believe that this results in work of so superior an order that the cost of the mistakes which may be made from time to time is paid for many times over by the greatly increased output of work of every official in the great telephone organisation of the Bell interest. Such an arrangement also has the merit of developing the most useful attributes of man, and hence there is no lack of the proper material for filling the highest administrative posts.

Telephones.

It seems hardly necessary for me to say much on the technical side of telephone engineering. We know how thorough our American cousins are in all they put their hands to. Their success is entirely due, in my opinion, to the scientific spirit in which they approach a subject. No changes are introduced until a complete investigation into each aspect of the situation has first been made. A novelty has to be "tested out" and "proved in" before it has any chance of acceptance. So far as service by means of the multiple switchboard is concerned, not much room for improvement has been left for some years past. However, American telephone engineers have not been content to rest on their oars, and many improved features of a minor character have been introduced into the service; for example, the study of traffic conditions has resulted in the introduction of the ancillary jack, which provides for calls appearing at two or more positions, and thus facilitates team working.

The question of the location of the trunk exchanges has not been, I fear, as deeply studied by us as the importance of the subject demands. In the case of the multi-office urban areas it is as necessary to study the economics of the location of the trunk exchange as it is to determine the theoretical centre for a local exchange. The problem is certainly a somewhat complex one to deal with, since it is difficult to assess the relative values of the variable factors which are introduced by the necessity of providing trunk circuits which must serve as sections of channels of communication between several widely separated areas as well as serving as direct channels between closely associated areas. In the case of many cities where the arbitrary attitude of the local authorities has caused us to contemplate the substitution of underground cables for aerial conductors, a study of the transmission efficiencies of those circuits which are built up of many component parts in order to provide a means of communication between the more widely separated centres has certainly indicated the desirability of erecting such conductors on pole lines constructed on routes outside the jurisdiction of disobliging corporations. The American telephone engineers have had seriously to face this problem, since not only do the cities in the United States cover immense areas, but at times the city authorities impose serious restrictions in the construction of open lines. In those cases in which a large number of trunks has to be provided for use, partly for local purposes and partly for extension or through traffic, the location of the exchange is determined by the section of copper required within the city limits to provide for transmission efficiency of the standards adopted for the circuits which have to be installed—that is to say, the question of cost in relation to the transmission efficiency required to meet the various traffic conditions is the ruling factor in deciding whether the trunk exchange shall be located within the city limits or outside the same. At three of the centres visited by me, Buffalo, Chicago and Philadelphia, the "long-distance" exchanges were situated at some distance outside the boundaries of these cities.

As was to be expected, a very complete study has been made of "loading" problems, and practical trials are being made over "loaded" aerial circuits. Many difficulties have been successfully overcome, and during my stay in New York an opportunity was afforded me of talking with Chicago on a "loaded" aerial circuit. The distance is about 1,000 miles, and the conductors are 420 lb. copper to the mile. Even under the adverse atmospheric conditions which prevailed it was quite possible to understand my correspondent in Chicago.

Some very useful information was given me concerning the interferences caused to long-distance telephone circuits by the electrification of railways, and ingenious methods have been devised for partly eliminating the disturbing currents, but the additional apparatus which has to be introduced into loops for this purpose seriously reduces the efficiency of the circuits for telephone purposes. The invention of telephone repeaters has received considerable attention, and they have been installed in quite a number of circuits, but unfortunately I had no opportunity of making observations on any circuits so equipped.

Automatic and Semi-automatic Exchanges.

Perhaps of all the interesting questions which were discussed, the most important is that relating to the development of the automatic and semi-automatic equipments. It was my good fortune to see no less than five different types of switch equipment, designed to provide automatic and semi-automatic telephone service, and I also had the advantage of discussing the question of providing service by means of these new types of equipment, not only with those who advocate these systems, but also with those who are opponents of the automatic systems. A matter which has been much debated is that relating to the probable attitude of the public towards a service provided by means of full automatic systems. The question naturally arises whether the public will take kindly to the task of calling their correspondents when once the novelty of the apparatus has worn off. I think the non-committal answer of "wait and see" is the safest at the present moment. True, at the present time, some 200,000 full automatic stations are in operation in North America, and the advocates of the system point to this fact in support of their contention that the public prefer this system. On the other hand, the opponents of the system claim that it is the novelty of the thing which appeals to the public, and suggest that the users are also stock-holders in the operating companies, that the pleasure arising from a feeling of ownership in the plant is responsible for the enthusiasm, where such exists, and that as soon as the plant begins to age, and the service in consequence shows signs of deterioration, the present feeling of satisfaction will give place to one of disgust. The whole question certainly requires the serious consideration of telephone engineers in this country. We have yet to learn from actual experience whether the automatic and the semi-automatic equipments provide sufficient flexibility to cover the wide range of requirements of the British public, how far the mechanism is reliable in the care of such men as we can train to maintain it, and how the cost of first installation and the annual charges in respect of depreciation, maintenance and traffic operation compare as a whole with similar costs in respect of existing types of installation. Clearly, if the new designs of equipment on "testing out" actually "prove in," there can be no doubt as to the course we must be prepared to adopt.

Comparative Costs of Electric Traction Systems.—In a Paper recently read by Mr. F. Darlington on this subject the author stated that estimates prepared for the electrification of about 100 miles of single-track railway, with about 25 miles of side tracks and with heavy gradients to be climbed and very heavy and frequent trains to be handled, showed the total cost of direct-current transmission and distribution apparatus, including sub-stations, to be £476,200, and for single-phase alternating current with transformer stations £202,200. These figures are based on 1,500 volts with a third rail for direct current and 11,000 volts with an overhead trolley for single-phase current. The difference in cost of the two distribution systems is £274,000. However, the single-phase locomotives for the same railroad would be more costly than direct-current locomotives by about £74,900, but this amount is only about one-quarter of the difference in the cost of the transmission and distribution appliances. In discussing the Paper, Mr. L. R. Pomeroy said that the advocates of electric traction had been dwelling on only a small portion of the various elements involved in the cost of transportation and that the effectiveness of engineering recommendations was somewhat diminished by the fact that the advice given was not always disinterested. He remarked that the electrical achievements thus far made, while mainly confined to passenger traffic, had shed little light, except in special cases, on the larger problem of freight train operation.

New volumes of "THE ELECTRICIAN" commence in April and October.

(This charge includes all Supplements.)

Vols. I. to LXIV. can now be supplied. Price on application.

"THE ELECTRICIAN" SERIES OF STANDARD ELECTRICAL BOOKS

can be obtained of all Booksellers at Home, in the Colonies, and Abroad.

THE "ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. Published annually in February, corrected to mid-February. Established 1882. A very valuable advertising medium, covering the entire Industry. SUBSCRIPTION Price (which is received *in advance* up to Dec. 31st in each year for the next following edition) 8s. 6d. nett, postage 9d. extra. Published price 15s. nett, postage 9d. extra. Postage to British Colonies, 2s. ; Europe, 2s. ; U.S.A., 3s. 6d. ; other countries, 2s. 6d. *Digest of Contents sent free on application.*

THE "G.T." GEOGRAPHICAL DIRECTORY OF THE U.K. (Electrical Section). Subscription 5s., post free.

"THE ELECTRICIAN" PRIMERS (81 Primers in all, and a GLOSSARY). Single Primers 3d. each post free. *New and Enlarged Edition in One Complete Vol. or Three separate Vols. now ready.* FULL PROSPECTUS FREE.

ELECTRIC TRACTION ON RAILWAYS. By Philip Dawson. Price 25s. nett. *Prospectus free.*

ALTERNATING-CURRENT MOTORS. By Dr. Rudolf Goldschmidt. Price 6s. 6d.

THE SHOT-FIRER'S GUIDE: A Practical Manual on Blasting and the Prevention of Blasting Accidents in Mines, Quarries, &c. By W. Maurice. Price 3s. 6d. nett.

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. Wilkinson, M.I.E.E. *New Edition.* Now ready. Price 15s. nett.

ELECTRIC BLASTING APPARATUS AND EXPLOSIVES: With Special Reference to Colliery Practice. By W. Maurice. Price 8s. 6d. nett.

THE ELECTRIC FURNACE IN IRON AND STEEL PRODUCTION. By John B. C. Kershaw, F.I.C. Price 3s. 6d. nett.

BRAKES FOR TRAMWAY CARS. By H. M. Sayers. Price 3s. 6d. nett.

THE MECHANICAL DESIGN AND CONSTRUCTION OF COMMUTATORS. By R. Livingstone. Price 6s. nett.

THE ALTERNATE-CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Prof. J. A. Fleming, M.A., D.Sc., F.R.S. [abroad 13s.

VOL. I.—Price 12s. 6d. post free, aoroad 13s. VOL. II.—Price 12s. 6d. post free,

HANDBOOK OF THE ELECTRICAL LABORATORY AND TESTING ROOM. Very fully illustrated. By Dr. J. A. Fleming. Vol. I., 12s. 6d. nett, Vol. II., 14s. nett.

ELECTRIC LAMPS AND ELECTRIC LIGHTING. By Prof. J. A. Fleming. 6s. nett.

ELECTRICAL LABORATORY NOTES AND FORMS. Arranged by Dr. J. A. Fleming, M.A., F.R.S. Single copies 4d. nett, or in dozens at 3s. 6d. nett. Complete Sets of 50 Notes and Forms, 12s. 6d. nett, or in strong portfolio, 14s. nett ; or bound in strong cloth, 15s. nett. Spare Copies of Tabular Sheets, 1s. per dozen. Portfolios, 1s. 6d. each. Sectional paper, 1s. per dozen sheets. *Complete Prospectus post free on request.*

A SMALLER SET of only 40 Forms, bound strong cloth. Price 7s. 6d. nett.

CENTENARY OF THE ELECTRIC CURRENT—1799-1899. By Prof. J. A. Fleming, F.R.S. Price 1s. ; strong cloth 2s. 6d.

ELECTRICITY METERS: THEIR CONSTRUCTION AND MANAGEMENT. By C. H. W. Gerhardi. Profusely illustrated. Price 9s. nett.

ELECTRICITY IN HORTICULTURE. By Prof. S. Lemstrom. Illustrated. 3s. 6d. nett.

RADIO-ACTIVITY: AN ELEMENTARY TREATISE, FROM THE STANDPOINT OF THE DISINTEGRATION THEORY. By Fredk. Soddy, M.A. Fully illustrated. Price 6s. 6d. nett.

ELECTROMAGNETIC THEORY. By Oliver Heaviside. Vol. I. Price 12s. 6d. Vol. II. Price 12s. 6d. *Vol. III. in the press.*

MOTIVE POWER AND GEARING FOR ELECTRICAL MACHINERY. By E. Tremlett Carter, C.E., M.I.E.E. Revised by G. Thomas-Davies, A.M.I.E.E., F.C.S. Price 12s. 6d. nett.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. Ewing, B.Sc., F.R.S., F.R.S.E. Price 10s. 6d.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. Kenneily and H. D. Wilkinson, M.I.E.E. Price 6s. 6d.

ELECTRIC MOTIVE POWER. By Albion T. Snell. Price 10s. 6d. nett.

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. Geipel and H. M. Kilgour. Price 7s. 6d. nett.

ELECTRICAL TESTING FOR TELEGRAPH ENGINEERS. By J. Elton Young. Price 10s. 6d.

STUDENTS' GUIDE TO SUBMARINE CABLE TESTING. By H. K. C. Fisher and J. C. H. Darby. Price 7s. 6d. nett.

SIGNALLING ACROSS SPACE WITHOUT WIRES: THE WORK OF HERTZ AND HIS SUCCESSORS. With new Chapter on Tuning. By Dr. Sir Oliver J. Lodge. Price 5s. nett.

THE ART OF ELECTROLYTIC SEPARATION OF METALS. By Dr. G. Gore, LL.D., F.R.S. Price 10s. 6d.

ELECTRO-CHEMISTRY. By Dr. George Gore. Price 2s.

BEGINNER'S MANUAL OF SUBMARINE CABLE TESTING AND WORKING. By G. M. Baines. Price 7s. 6d. nett.

CARBON MAKING FOR ALL ELECTRICAL PURPOSES. By Francis Jehl. Price 10s. 6d.

THE ELECTRICIAN" WIREMAN'S POCKET BOOK. Edited by F. C. Raphael. Price 5s. nett.

"THE ELECTRICIAN" HANDY WIRE TABLES FOR THE POCKET. By P. B. Down, Wh.Ex., A.M.I.Mech.E. Price 2s. 6d. nett.

THE RATING OF ELECTRIC LIGHTING, ELECTRIC TRAMWAY, AND SIMILAR UNDERTAKINGS. By W. G. Bond, M.I.E.E. Price 2s. 6d. nett.

DRUM ARMATURE WINDING AND COMMUTATORS. By F. M. Weymouth. 7s. 6d.

PRIMARY BATTERIES: THEIR CONSTRUCTION AND MANUFACTURE. By W. R. Cooper. Price 10s. 6d. nett.

SECONDARY BATTERIES: THEIR CONSTRUCTION AND MANUFACTURE. By E. J. Wade. Price 10s. 6d. nett.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. Price 1s. 6d.

THE LOCALISATION OF FAULTS IN ELECTRIC LIGHT CABLES. By F. C. Raphael. 7s. 6d.

THE STEAM-ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. Beaumont, M.I.C.E., M.I.M.E., &c. Price 6s. nett.

THE ELECTRIC ARC. By Mrs. Ayrton, M.I.E.E. Price 12s. 6d.

TRAMWAY TRACTIVE EFFORT AND POWER DIAGRAM. By Arnold G. Hansard, B.A., A.M.I.E.E. Price 4s. 6d. nett ; in Tube, 5s.

THE BRITISH POST OFFICE TELEPHONE SERVICE. Fully illustrated.. Price 3s. 6d. nett.

INTERNATIONAL TELEGRAPH CONVENTION AND SERVICE REGULATIONS. Price 6s. nett. (LISBON REVISION, 1908.)

BOILER FEED WATER. By F. W. Anderson. Price 6s. nett.

(PRELIMINARY) WIRELESS TELEGRAPH CONFERENCE (BERLIN, 1903), PROCEEDINGS AT. Price 8s. 6d. nett.

INTERNATIONAL WIRELESS TELEGRAPH CONVENTION AND SERVICE REGULATIONS (BERLIN, 1906). With complete report of Proceedings. Price 21s. nett.

THE CLASSIFICATION OF ALTERNATE-CURRENT MOTORS. By V. A. A. Fynn, M.I.E.E. Price 3s. nett.

ELECTRIC CRANES AND HOISTS. By H. H. Broughton. *In Preparation.*

PRACTICAL TELEPHONY. By W. Aitken, M.I.E.E. *In Preparation.*

ELECTRIC MAINS AND DISTRIBUTING SYSTEMS. By J. R. Dick, B.Sc., and F. Fernie, A.M.Inst.C.E. *In Preparation.*

THE PRACTICAL WIRELESS SLIDE RULE. By Dr. H. R. Belcher-Hickman. Price 2s. 6d. nett. *Nearly Ready.*

THE MECHANICAL DESIGN AND CONSTRUCTION OF GENERATORS. By R. Livingstone. *In Preparation.*

LIGHT, RADIATION AND ILLUMINATION. From the German of Paul Högner, by Justus Eck. *In Preparation.*

"THE ELECTRICIAN" INDUSTRIAL SUPPLEMENT.

With "THE ELECTRICIAN" for Sept. 14, 1906, was issued the first of a series of "Industrial Supplements," to be published from time to time with "THE ELECTRICIAN." The fifty-first issue of the Supplement is published (Gratis) with the current number of "THE ELECTRICIAN."

The "INDUSTRIAL SUPPLEMENT" is a comprehensive record of developments in Electrical Plant, Machinery, Apparatus, Accessories, Sundries and Materials, and of their proved suitability for various Industrial purposes.

The "INDUSTRIAL SUPPLEMENT" is holed for filing or hanging, and filing covers can be supplied for holding 6 or 12 issues.

SPECIAL NOTICE.

NOW READY.—Vol. LXIV. of "THE ELECTRICIAN" (1,085 pages) bound in strong cloth. Price 17s. 6d.; post free, 18s. 6d. Now ready. Cases for Binding. Price 2s.; post free, 2s. 3d.

A complete set of "THE ELECTRICIAN" can be supplied. A number of odd volumes and some odd old back numbers, to help in making up complete sets, are also available.

THE ASSOCIATION OF CONSULTING ENGINEERS.

For the last two years we have strongly advocated the formation of a society for protecting the interests of consulting engineers, and we have pointed out from time to time the futility of expecting any existing institution to carry out the work that is really necessary. An attempt to stop the unprofessional conduct that was bringing consulting engineering into disrepute was made some years ago by the Institution of Electrical Engineers, but it in no wise prevented the malpractices which the Institution had in view, and at the same time it weakened, if anything, the hands of those consulting engineers who wished to act in a truly professional spirit. Last year the Institution of Civil Engineers took the matter up, and adopted a certain code of rules, and this year the Institution of Electrical Engineers have taken further action by adopting identically the same rules as those of the parent Institution. But, however good the intention of such rules may be, it is impossible to expect bodies representing so many varied interests to legislate very effectively for one particular group, and that group by no means a large percentage of the whole.

In another column our readers will see that steps have now been taken to form an Association of Consulting Engineers. We heartily welcome this movement. For the last two years the matter has been under consideration, and, although it may seem that progress has been slow, there is every

Digitized by Google

indication that a very good beginning has now been made. It will be noticed that the new Society is not restricted to the electrical profession. It embraces civil engineers (using the term in its more restricted sense) and gas engineers as well, so that a very large field of engineering is covered. Also, there need be no fear that the new Society is in any sense run by a clique, as the invitation to attend the meeting held last week was backed by names which were certain to carry weight, and a representative gathering was the result. The proceedings showed entire unanimity of opinion, and the committee that was elected to carry the matter forward cannot fail to bring the Society into prompt recognition.

It may be well to point out that the new Society is in no way antagonistic to existing societies, and that it does not propose to read technical Papers, or to add to that output of technical literature which many people feel to be already too large. This assurance will come as a relief to any of our readers who may have had such an idea. Primarily the object is to raise the standard of the profession of consulting engineering. We, therefore, hope that it will be supported by the goodwill of many who are not themselves consulting engineers. For example, there is the general public. Hitherto there has been no easy means of finding out who was, or who was not, a consulting engineer; much less was there any means of determining the qualifications of any engineer who styled himself a consultant. From the point of view of the public this was very unsatisfactory, and has doubtless led to the carrying out of a great deal of indifferent work, and has produced much dissatisfaction. As mentioned by Mr. MIDGLEY TAYLOR at the meeting last week, there is nothing to compel a municipal authority to employ a properly qualified man to advise them, even in works of large magnitude; and if such a man is appointed, attempts to dislodge him in favour of an engineer with doubtful qualifications, and who does not mind touting for the work, are not unknown. Nor is this the only way in which the public may suffer. If the programme of the new Society is carried out, the public will feel that some protection is provided, as the tendency will be to employ only those consulting engineers who are members of the Society; and the fact that they are members will be some guarantee of their qualifications and that they are guided by the recognised rules of professional conduct.

It is equally important, however, that other engineers should recognise that the new Society will aim at the greater well-being of all things connected with consulting engineering, and in this respect we hope very sincerely that manufacturers and contractors will support the new movement and recognise that it is really to their advantage. There have been many complaints in the past of consultants who were not properly qualified, or who did not scruple to take advantage of the contractor in an unfair way. The true consultant acts in a semi-judicial capacity, and sees that not only does his client receive what is specified, but that the contractor also obtains fair play. It is to be hoped that unfair episodes will end once for all with the formation of the new Society, and we, therefore, trust that manufacturers and contractors will give it their cordial support.

REVIEWS.

Radiation, Light and Illumination. By C. P. STEINMETZ. (New York: The McGraw Hill Book Co.) Pp. xii. + 788. $3 net.

In the volume now before us we have another instance of the protean character (if the allusion may be pardoned) of Prof. Steinmetz's work. To most of us the author is known principally in connection with his extensive mathematical investigations on alternate-current phenomena, and his practical applications of this theory to electrical machinery. Those, however, who have been privileged to visit his private laboratory at Schenectady know that the problems of light production have had a special fascination for Prof. Steinmetz for many years past, and some of his work in this direction, notably as regards the magnetite arc, has been followed here with interest.

In the volume now before us we have the substance of a series of 13 lectures delivered at Union University. Unfortunately, no verbatim report was made, and Prof. Steinmetz has been obliged to leave the editing in other hands, with the result that a number of small errors have crept in; but, even so, the book is most valuable as being the only treatise which deals in a comprehensive and original manner with a subject which becomes daily of greater interest and importance.

The first chapter, or lecture, deals with the nature and different forms of radiation in a simple and clear manner. In introducing the undulatory theory, however, its inception is ascribed to Euler, and no mention is made of Huyghens, Young or Fresnel. On the same page two beams of light of equal amplitude and coincident phase are stated to give twice, instead of four times, the intensity of one. In dealing with X-rays on pp. 15-17, they are spoken of as oscillations having a wave-length of about $0{\cdot}01 \times 10^{-6}$ cm., although the view now more generally accepted is that they consist of sharp individual pulses produced by electronic impact. On p. 16 the blank space between the *longest* electric and the *shortest* ultra-violet light is spoken of. In the second lecture, on the relation of bodies to radiation, simple physical explanations of refraction and dispersion are given by the wave theory, of emission and absorption spectra, of reflection, colour and fluorescence. The author speaks of the *actual* or *objective* colour of a body, and also its *subjective* colour when viewed by a coloured source. The terms *absolute* and *relative* colour would perhaps be better, reserving *subjective* colour for the effect on the observer, who might be colour blind. On p. 30 lamp black is instanced as a black body, but not platinum black. The term *albedo* is employed to denote the whiteness of a grey body, being a coefficient which is unity for a perfectly white and zero for a perfectly black surface. A very interesting lecture is devoted to the physiological effects of radiation, starting with a description of the eye and of Fechner's law. In common with other writers on the subject, however, the author does not differentiate between the functions of the pupil and the retina in connection with this law. The useful and injurious effects of various kinds of radiation on the eye and the body are remarkably well treated.

Incidentally, the mechanical equivalent of light is given as having a value of 0·01 watt per candle, which is probably far too low.

After a short lecture on the chemical and physical effects of radiation, the laws of temperature radiation are discussed in lecture V. The Stefan-Boltzmann law (spelt Stephan) is given with a coefficient of $5' \times 10^{-12}$ which is lower than that of Karlbaum ($5{\cdot}32 \times 10^{-12}$) and of Féry ($6{\cdot}3 \times 10^{-12}$). Wien's and Planck's laws are quoted, but full justice is not done to their utility as regard temperature measurement and luminous efficiency. The classification of elements according to their melting points and the periodic law is done in a very effective diagram; the use of the term vapour *tension* is, however, objectionable. Carbon as a radiator is fully dealt with, and interesting remarks are made on the peculiarities of carbon produced in flames from various combustibles.

Digitized by Google

Lecture VI., on luminescence, is one of the most interesting in the book, as it deals largely with Prof. Steinmetz's work on arcs, mercury, carbon, magnetite, &c. Several most original experiments as to the non-reversibility of the arc are quoted, and incidentally the value of the old "exploring carbons" as a method of investigating the distribution of potential in the arc is completely exploded. The titanium arc is described as having a consumption of 0·25 watt or less per mean spherical candle, but little mention is made of the quartz mercury vapour lamp.

The chapter on flames as illuminants and arc lighting are both interesting, but one would like to have seen more about the Welsbach and other mantles. However, some good works already exist on this subject. Lecture IX., on the measurement of light and radiation, is somewhat disappointing, photometry being treated in a very sketchy fashion and radiation measurement hardly touched. It is satisfactory to find that Prof. Steinmetz advocates discrimination as the basis of heterochromatic photometry, but the "luminometer" he describes is a very crude instrument, and no mention is made of the use of an artificial pupil, which is such an important adjunct. Two very complete lectures are given on light flux and illumination, with most exact calculations as to the light distributed from and received with various sources. Finally, two excellent lectures are devoted to illumination and illuminating engineering and to physiological problems, which are in every way most interesting and instructive, especially in connection with the present discussions concerning glare.

Prof. Steinmetz's new work will doubtless be read with attention by all interested in this important subject, and we hope that it will soon reach a second edition, when he will be able to perfect it.

C. V. DRYSDALE.

Les Oscillations Electriques: Principes de la Télégraphie sans fil. By C. TISSOT. (Paris: Doin & Fils.) Pp. xii. + 454. Fr. 5.

This volume is one of the Encyclopédie Scientifique series. It deals with the physics, as distinct from the technology, of electrical oscillations. Mathematical argument and experimental fact are agreeably blended throughout the work, but the former predominates. In the first 50 pages the reader is introduced to the general theory and formulæ of simple harmonic and damped harmonic vibrations. Then the laws of ordinary alternating current are discussed. The study of high-frequency electricity begins with a chapter on the production of oscillations, and proceeds with an account, mainly historical, of the work of Hertz and others on the propagation of electrical waves along wires and through space. The physics here is thoroughly up to date; that of the spark is set out in considerable detail, but that of the arc is not so fully treated as it might have been with advantage. The remainder of the book is almost entirely mathematical, and may be described as a summary or abstract of Hertz's discussion of the radiation from an oscillator and of the theory of the oscillations in coupled circuits as given by Bjerknes, Oberbeck, Wien and Drude. This summary, though purely academical, should prove useful to technical men, as it is written with an eye to modern applications and is otherwise very good. It will be seen from this survey of the book that it fills a very apparent lacuna in French electrical literature.

ANALYSIS OF LEAKAGE REACTANCE.

BY J. REZELMAN.

Summary.—The author continues his investigations into the leakage of the windings of alternating-current machines. The expression for the permeance λ_k is considerably simplified and made much more general; the expression for the slot permeance, too, is slightly modified. The leakages of many machines have been carefully analysed and the results are here given. Bar windings also are dealt with.

In the Paper on "Leakage Reactance," recently published by the author, certain coefficients have been introduced, their values having been found by experiment.

These coefficients vary with the type of winding, and we shall see in the following that it is necessary to make certain corrections in order that the formulæ shall become general. For this purpose we will consider a two-phase winding, and utilise the well-known property of the independence of the phases.

1. *Permeance* λ_k.—It has already been shown that

$$\lambda_k = 0{\cdot}92\left\{\log\left(\frac{\pi z_1}{r_1}\right) + C_q + q\log\left(\frac{\tau}{(q-1)t_1}\times B\right)\right\}$$

in which the first term—$\log\left(\frac{\pi z_1}{r_1}\right)$—relates to the flux between the tips of neighbouring teeth, the factor C_q to the flux between the teeth which are not adjacent, and the last term to the flux embracing all the slots per pole and phase; τ represents the extent of the integration, and B a factor taking account of the curvature subtended by the polar arc.

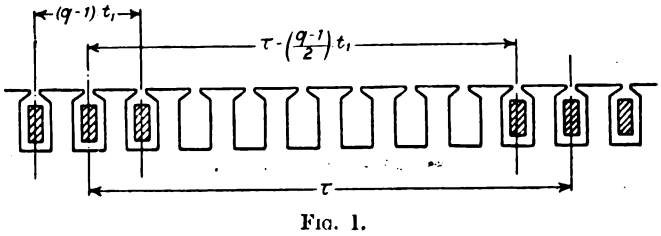

FIG. 1.

Let $\tau = Qt_1$ where Q = number of slots per pole; then the last term becomes $q \times \log\left(\frac{Q}{q-1}\times B\right)$. By inspection it is seen that the summation ought not to be carried over the whole polar arc; in fact, starting from $\tau - \frac{1}{2}(q-1)t_1$ (Fig. 1) the flux does not embrace most effectively all the slots per pole and phase.

We will integrate for a length $x = (Q - cq)t_1$ and have $\lambda_k = 0{\cdot}92\left\{\log\frac{\pi z_1}{r_1} + C_q + q\log\left(\frac{Q-cq}{q-1}\right)\right\}$, assuming that B = 1, that is to say, that the number of poles is very great.

To find the value of C, consider the case of a winding covering the whole polar arc ($q = Q$), in which case the last term $Q\log\left(\frac{Q-cQ}{Q-1}\right) = 0$; that is to say,

$$(Q - cQ)/(Q-1) = 1$$

and

$$c = 1/Q.$$

In general the last term will thus become: $q\log\left(\frac{Q - \frac{1}{Q}\times q}{q-1}\right)$, and we obtain for

$q = \frac{1}{2}Q$, that is, for one phase of a two-phase winding: $q\log\left(\frac{4q-1}{2q-2}\right)$.

$q = Q$, that is, for two phases in series of a two-phase winding: $q\log\frac{q-1}{q-1} = 0$.

$q = \frac{1}{3}Q$, that is, for one phase of a three-phase winding: $q\log\left(\frac{9q-1}{3q-3}\right)$.

$q = \frac{2}{3}Q$, that is, for two phases in series of a three-phase winding: $q\log\left(\frac{9q-4}{6q-6}\right)$.

It is well known that the permeance of one phase of a two-

Digitized by Google

phase winding ($q=\frac{1}{2}Q$) is the same as that of the two phases in series ($q=Q$), it follows, then, that

$$C_q + q \log\left(\frac{4q-1}{2q-2}\right) = C_{2q}, \text{ and, for example, with } q=2:$$

$$C_2 + 2\log\left(\frac{4\times 2-1}{2\times 2-2}\right) = C_4, \text{ whence } C_4 = C_2 + 1{\cdot}09.$$

Now, the factor C only depends on the number of slots per pole and phase, and is zero for $q=2$, whence $C_4 = 1{\cdot}09$. Proceeding in this manner we have

$$C_4 + 4\log\left(\frac{4\times 4-1}{2\times 4-2}\right) = C_8, \text{ whence } C_8 = 1{\cdot}09 + 1{\cdot}59 = 2{\cdot}68,$$

and similarly

$$C_8 + 8\log\left(\frac{4\times 8-1}{2\times 8-2}\right) = C_{16}, \text{ whence } C_{16} = 2{\cdot}68 + 2{\cdot}76 = 5{\cdot}44.$$

The four values of C_2, C_4, C_8 and C_{16} enable us to plot the curve (Fig. 2), from which the values of C corresponding to intermediate values of q can be determined.

For a given type of winding the last term $q\log\left(\frac{Q-q\times 1/Q}{q-1}\right)$ has a value which, like C, only depends on the number of slots

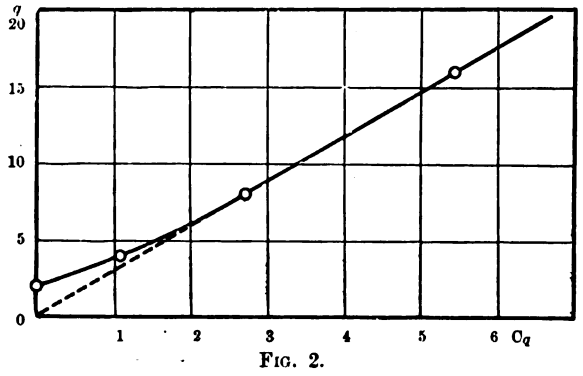

FIG. 2.

per pole and phase; we can thus combine these terms and write

$$D_q = C_q + q\log\left(\frac{Q-\frac{1}{Q}\times q}{q-1}\right).$$

We thus obtain, for a large number of poles,

$$\lambda_k = 0{\cdot}92\left\{\log\frac{\pi\times z_1}{r_1}\right) + D_q\right\}$$

where D_q has the values given below.

q.	Values of D_q for			
	$q=\frac{1}{2}Q$.	$q=Q$.	$q=\frac{1}{3}Q$.	$q=\frac{2}{3}Q$.
2	1·1	...	1·51	...
3	1·97	...	2·57	...
4	2·70	1·1	3·45	2·10
5	3·41	...	4·35	...
6	4·10	1·93	5·22	3·26
7	4·76	...	6·05	...
8	5·46	2·70	6·93	4·37
9	6·10	...	7·75	...
10	...	3·40	...	5·42
12	...	4·10	...	6·48
14	...	4·78	...	7·50
16	...	5·45	...	8·52
18	...	6·10	...	9·52

An examination of the above table shows that there is almost an exact proportionality between D_q and q, so that

$D_q = 0{\cdot}68\times q$ for a winding in which $q=\frac{1}{2}\times Q$.
$D_q = 0{\cdot}34\times q$ for a winding in which $q=Q$.
$D_q = 0{\cdot}875\times q$ for a winding in which $q=\frac{1}{3}\times Q$.
$D_q = 0{\cdot}545\times q$ for a winding in which $q=\frac{2}{3}\times Q$.

We have now to determine the augmentation of the permeance due to the curvature of the polar arc; we must thus add a term of the form $x_q\times q\log B$, where B is a factor depending upon the number of poles on the machine.

We write $x_q\times q$, being given that there is a contraction of the lines of force corresponding to C_q as well as to $q\times\log\left(\frac{Q-q}{q-1}\right)$; the coefficient x depends, therefore, on the number of slots per pole and phase. In addition, to fulfil the condition that the permeance of a winding $q=\frac{1}{2}Q$ is equal to that of a winding $q=Q$, it is necessary that $x_q\times q\times\log B = x_{2q}\times 2q\times\log B$, that is to say, $x_q = 2x_{2q}$.

By putting $x=1$ for a winding in which $q=\frac{1}{2}Q$, it follows that $x=0{\cdot}5$ for a winding $q=Q$. It being given that D_q varies in direct proportion to q for the same type of winding, we can take, with a very close degree of accuracy:

$x=1{\cdot}3$ for a winding $q=\frac{1}{3}Q$

and $x=0{\cdot}8$ for a winding $q=\frac{2}{3}Q$.

The complete formula thus becomes

$$q=\tfrac{1}{2}Q,\quad \lambda_k = 0{\cdot}92\left\{\log\left(\frac{\pi z_1}{r_1}\right) + 0{\cdot}68q + 1\times q\log B\right\}$$
$$= 0{\cdot}92\left\{\log\left(\frac{\pi z_1}{r_1}\right) + q\left(0{\cdot}68 + \log B\right)\right\}$$

$$q=Q,\quad \lambda_k = 0{\cdot}92\left\{\log\left(\frac{\pi z_1}{r_1}\right) + 0{\cdot}34q + 0{\cdot}5q\log B\right\}$$
$$= 0{\cdot}92\left\{\log\left(\frac{\pi z_1}{1}\right) + 0{\cdot}5q\left(0{\cdot}68 + \log B\right)\right\}$$

$$q=\tfrac{1}{3}Q,\quad \lambda_k = 0{\cdot}92\left\{\log\left(\frac{\pi z_1}{r_1}\right) + 0{\cdot}875q + 1{\cdot}3q\log B\right)$$
$$= 0{\cdot}92\left\{\log\left(\frac{\pi z_1}{r_1}\right) + 1{\cdot}3q\left(0{\cdot}68 + \log B\right)\right\}$$

$$q=\tfrac{2}{3}Q,\quad \lambda_k = 0{\cdot}92\left\{\log\left(\frac{\pi z_1}{r_1}\right) + 0{\cdot}545q + 0{\cdot}8q\log B\right\}$$
$$= 0{\cdot}92\left\{\log\left(\frac{\pi z_1}{r_1}\right) + 0{\cdot}8q\left(0{\cdot}68 + \log B\right)\right\}$$

Applied to various machines on which λ_k has been determined by means of auxiliary coils, the following values of B were found:—

H.P.	p.	q.	Q.	B.	$(p+1)/p$.
220	1	5	15	1·9	2·0
220	1	10	15	1·96	2·0
4,500	2	4	12	1·545	1·5
4,500	2	8	12	1·6	1·5
175	3	6	12	1·36	1·33
175	3	12	12	1·36	1·33
175	4	3	9	1·23	1·25
175	4	6	9	1·24	1·25

It follows from the above table that the value $(p+1)/p$ can be taken for B.

2. *Permeance* λ_s.—In order to determine the accuracy of the formula $\lambda_s = 0{\cdot}46q_s\left(\log\frac{2l_s}{U_s} + A\right)$, experiments were carried out on the rotor coils of a turbo-alternator; the dimensions of these coils were in agreement with those normally met with in practice. Each coil consisted of 36 bars (1·7 × 21), arranged as in Fig. 3.

Table of Experiments.

Readings with a current of 10 amperes in coil.	Voltage measured on coil.					Current.	Freq.	Watts measured.	I^2R	$\frac{W}{I^2R}$

Digitized by Google

The wattmeter readings show that there are important additional losses; on making the corrections necessitated thereby, we obtain the following table:—

Coil.	Voltage.	Reactance.	Coil.	Voltage.	Reactance.
a	6·25	0·625	c	4·5	0·450
$a+b$	19·5	1·950	$c+d$	13·4	1·340
$a+b+c$	36·8	3·680	d	3·5	0·350
$a+b+c+d$	53·3	5·330	$d+b$	13·1	1·310
b	5·5	0·550	$a+d$	13·4	1·340
$b+c$	16·67	1·667	$a+c$	15·6	1·560
$b+c+d$	30·05	3·005			

The reactance

$$x_s=\frac{12\cdot5\times c\times w^2}{10^8}\times l_s\times\lambda_s=\frac{12\cdot5\times 50\times w^2}{10^8}\times l_s\times 0\cdot46\left(\log\frac{2l_s}{U_s}\times A\right)$$

$$=\frac{288w^2}{10^8}\times l_s\left(\log\frac{2l}{U_s}\times A\right).$$

l_s being the length of a half-turn and $c=50$, we have the lines of force through the coils themselves; A would probably have larger values with wire windings. In any case, it follows from the tables that the permeance varies sensibly according to the expression $\log\frac{2l_s}{U_s}$, and that it is essential in exact calculations that the circumference U_s should be introduced.

It would then be useless to use these experiments as a sole basis for determining the relationship between A, and at the same time R, and the dimensions of the coils; moreover, we shall see, from experiments made with this especial purpose on the stator of a three-phase 175 H.P. motor that the formula we have previously employed, is in perfect agreement with the nature of the actual phenomena.

Stator of a three-phase motor, 175 h.p., 8 poles, 50 cycles per second, 750 revs.; 3,000 volts between phases, the rotor being removed.

Coils in series.	l_s	U_s	$\frac{2l_s}{U_s}$	$\log\frac{2l_s}{U_s}$	w^2	$\frac{288w^2l_s}{10^8}$	$\frac{288w^2l_s}{10^8}\times\log\frac{2l_s}{U_s}$	x_s measured.	$\frac{288w^2l_s}{10^8}\times A$	A	R = x_s measured / x_s calc. (A = 0)

By taking the average value A = 0, the maximum deviation between the calculated and measured values only reaches ± 6 per cent., depending on the various shapes of the sections; it is

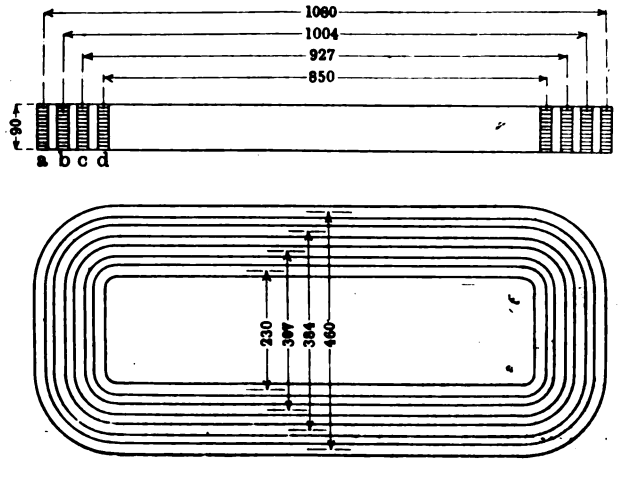

Fig. 3.

to be noted that a small error in the measurements will have a considerable effect upon the value of A, but only a small effect on the ratio $\frac{x \text{ measured}}{x_s \text{ calculated } (A=0)}$. In spite of great care the table shows that there are errors up to 5 per cent.; it is necessary that

(Line a.)		Line (a).		Line ($a+b$).
e_a	+	e_b	≷	e_{a+b}

that is to say, 6·4 + 4 ≷ 10·8;

similarly

(Line a.)		(Line b.)		(Line $a+b$.)
e_a+e_b	+	e_a+e_b	≷	e_a+e_b,

that is to say, 6·4 + 4 + 4 + 5·6 ≷ 10·8 + 9.35.

In addition, the flat copper impedes the free formation of

Dimensions.

$\phi_i=750$ mm. ..... $\tau=294$ mm.
$l=270-3\times7\cdot5$ mm. ..... $l_i=260$ mm.
72 slots (19 × 50) ..... $t_1=32\cdot7$ mm.
$S_n=23$ $p=4$ $q=3$.

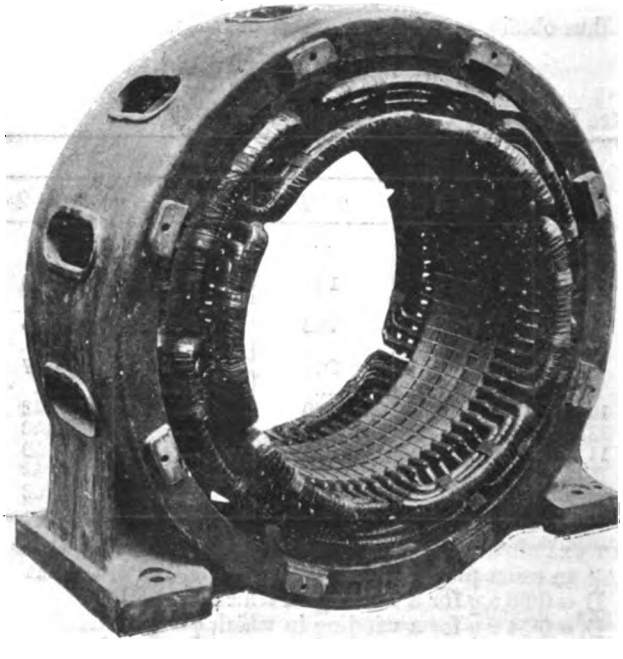

Fig. 4.

The stator of this motor is wound with consequent poles, there are thus four coils per phase; the 12 coils are arranged in two planes containing two coils of each phase (Fig. 4). It follows from this arrangement that the six coils in each plane can be connected in series and thus form a two-phase six-pole winding, with a split-phase winding, or winding per pole.

Digitized by Google

The dimensions become

$\phi_s = 750$ mm. ..... $\tau = 392$ mm.
$l = 270 - 3 \times 7{\cdot}5$ mm. ..... $l_i = 260$ mm.
72 slots (19 × 50) mm. ..... $t_1 = 32{\cdot}7$ mm.
$S_s = 23$ p = 3 q = 6.

By a simple change in the connection of the coils we have thus transformed a winding per consequent pole into a winding per pole; the lengths of the outhang coils are the same for the two cases:

$l_s = 680$ mm., $l_{s_a} = 360$ mm, $l_{s_c} = 320$ mm.;

and also the periphery $U_{s_a} = 210$ mm. With the periphery U_{s_c} the values are not the same for the two cases.

In three-phase $U_{s_c} = 210$ mm., and in two phase $U_{s_c} = 470$ mm.

In order to separate the permeances λ_h, λ_s and λ_n experimentally, auxiliary coils were placed:—

1. Five wires in the slot opening of each of the three slots forming one coil, along the stator bore, the length of the slots of one pole;
2. 20 wires along l_i of one coil, in each of the two intervals.

Experiments.—Readings were taken:—

1. On one-phase of the three-phase winding.
2. On two phases in series of the three-phase winding.
3. In three-phase.
4. On one-phase of the two-phase winding.
5. On two phases in series of the two-phase winding.
6. On one coil separately, three slot coils, *a*, *b* and *c*.
7. On two slot coils, *a* and *b*.
8. On two slot coils, *b* and *c*.

Table of experiment.	Winding.	$e_{0-I.}$	$e_{I.-II.}$	Voltages on the auxiliary coils. e_h. Mea.	e_h. Red.	e_s. Mea.	e_s. Red.	I.	c.

Notes on the Test.—It is established that for a constant current of 10 amperes the voltage set up in the exterior auxiliary coils depends upon the winding traversed by the current.

1. One phase of three phase winding ..... 2·33 volts.
2. Two phases in series of three-phase winding 2·42 volts.
3. Three-phase ..... 2·44 volts.
4. One phase of two-phase winding..... 3·50 volts.
5. Two phases in series of two-phase winding 3·43 volts.
6. One coil separately ..... 2·84 volts.

It is also established that there is a slight positive mutual induction between the end coils of a three-phase winding, although wound per consequent poles. The chief point established consists in that the voltage induced in the exterior auxiliary coils, by one coil alone, is markedly greater than that induced by one phase of the three-phase winding.

The values l_i and U_s being the same in the two cases, this increase can only be put down to the absence of a demagnetising force, which thus proves experimentally the presence of an important negative mutual induction between the neighbouring coils of a consequent pole winding.

(To be continued.)

Hydro-Electric Development in Sweden.—According to the "Engineer," the Swedish Government intend to expend over a million sterling upon the establishment of an electric power station at the Porjus Falls, which are on the Stora Lule River, near the Gellivare iron district. Great hopes are entertained that a large industry will arise in the regions affected.

CORRESPONDENCE.

FISCAL POLICY AND THE ELECTRICAL INDUSTRY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I must once more remind Mr. Fitch that national prosperity depends not on the profits of employers but on the total production of wealth. I know how difficult it is for a manufacturer to realise this, but it must be realised if the subject is to be understood and usefully discussed. Also that, if there is a choice of producing for the home market or for a foreign market, the foreign market has the greater advantage for the working man. We, as the principal dumpers of the world, do our foreign trade at the lowest possible profit; and, consequently, in this trade, labour bears the greatest proportion to total value. In other words, the workman's share is larger as compared with the employer's.

For the rest, I am sure it would be better if your Tariff Reform correspondents would leave out of account the subject of my ignorance and want of intelligence and candour, as being of no general interest, and answer the simple question that I ask. It is, as I have said, fundamental; and if it is not answered Tariff Reform falls to the ground, notwithstanding the defects that they discover in me. Can they give the steps in the argument by which it is shown that Tariff Reform would increase employment, without assuming that imports are paid for with "golden sovereigns"? I gave the steps in the argument by which it is shown that Tariff Reform would reduce employment. This also remains unanswered. And that is how we stand at present—an argument for reduction; no argument for increase.—I am, &c.,

Birmingham, July 20. GEORGE HOOKHAM.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I shall be glad if you will allow me a little space in which to reply to Mr. Bennett Fitch's letter in your issue of July 15th.

Mr. Fitch cites a hypothetical case. He asks us to suppose a case where "Smith's grandfather some 50 years ago made money and left him an income of £200 a year invested in a railway in Brown's country, this income being quite outside the trading question. Smith hears that motor cars, &c., are made very cheaply abroad, and writes to Brown not to send the £200, but to send instead that amount in motor cars, &c., as they are cheaper than he can make them at home. Under these circumstances the balance of money would remain equal. Our workers would lose profits and wages to the extent of £200 (less the value of raw material)."

Mr. Fitch's own words place him quite out of court as an economist, for it is the height of absurdity to claim that Smith's income can be regarded as being "quite outside the trading question." It is not, and cannot be, outside the question, for it implies the investment at a previous date of, say, £4,000 (which at 5 per cent. would bring in the £200 per annum) in the railway in Brown's country, which I will assume to be France. That £4,000 represents, directly or indirectly, British goods or British labour, and Smith's annual income of £200 is in the nature of the profit on the British labour expended. Mr. Fitch's case assumes that the motor car can be made more cheaply in France than here. Suppose Smith gets for his £200 a car which would have cost him here £250; what does it mean? Simply that Smith is £50 in pocket on the transaction, and this £50 he can spend in this country on other goods which will in turn find employment for British workers.

As a matter of fact, the purchase of the motor car is quite a separate transaction. Smith's grandfather employed British labour, and invested the proceeds in France, and Smith draws the profit; that is one complete transaction. Smith, having got his £200, can do what he likes with it, and, being a sensible man, he buys something which he needs in the cheapest market where he can get it. That is a second and quite separate transaction.

Digitized by Google

Returns show that the goods which come into this country in payment of interest on our investments abroad are in an overwhelming proportion in the nature of raw materials, which, to quote the words of another of your correspondents, ensure a great gain of employment to the country.

Mr. Fitch is amusing when he quotes a German Protectionist newspaper to show that England is a decadent country. Judging from the Board of Trade returns for the present year we can afford to go on "decaying" at our present rate for quite a long time to come.

Mr. Glendenning, in his letter in your issue, says the primary object of scientific tariffs is the exchange of our manufactures for the other nation's raw material. But why adopt a tariff, "scientific" or otherwise, when we already attain that object by our Free Trade system?—I am, &c.,

Free Trade Union, Manchester, July 18. J. ANDERSON.

LIQUID MICROPHONES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your issue of July 15, 1910, a liquid microphone by Mr. F. J. Chambers is described. I think that Mr. Chambers is to be congratulated on his application of a liquid microphone to large currents as used in wireless telegraphy. I may mention that in the year 1879 I made and used a liquid microphone ("Nature," October, 1879, and the "Telegraphic Journal," November, 1879) in which the area and hence the resistance of a small column of a liquid conductor, either stationary or flowing, was controlled by the vibrations of a diaphragm attached to a glass valve which controlled the flow. Subsequently, in November, 1892, I constructed a liquid rheostat, which acted as a transmitter or microphone, in which a jet of conducting liquid flowing on to a platinum plate inclined at an acute angle to it was actuated by a vibrating diaphragm. When these liquid microphones were put into a telephone circuit the articulation was excellent, quite smooth and free from grating sounds. Experiments with the latter were shown at the Junior Science Club, Oxford, in 1892. I never experimented with currents of large value such as employed by Mr. Chambers, nor did I follow the matter up, as experts in telephonic work seemed to think that the employment of a liquid would render the apparatus unfit for practical telephony.—I am, &c.,

Lymington, July 18. F. J. JERVIS-SMITH.

SUGGESTED MEMORIAL TO THE LATE H. W. COX.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Will you open a fund for raising a memorial to the late H. W. Cox? When a naval or military man performs some heroic deed in war it is customary, I believe, for the commanding officer to refer to it in his report to the home authorities. When the man who has done the brave deed returns home he is perhaps decorated by his Sovereign with the Victoria Cross "For Valour." And when the warrior dies, it sometimes happens that a statue is erected to his memory by a grateful country.

Now, I know, Sir, that in such a civil profession as electrical engineering, whatever heroism a man may display, there is no such thing as being mentioned in despatches, or receiving a V.C. It is possible, however, to follow the example of a grateful country and raise a memorial to a man who has shown as much bravery as any sailor or soldier.

On these grounds I am asking you, Sir, to invite subscriptions from those who know and appreciate the work done by H. W. Cox.

I would suggest that the memorial consist of a sum of money to help to keep the wife and family of a man who has laid down his life for his fellow men. I am, &c.,

Faraday House, Southampton-row, London, W.C., July 18. CHRISTOPHER SILVER.

[We shall be pleased to accept subscriptions as suggested, and to hand them over to any committee authorised to act in the matter.—ED. *E.*]

LOANS FOR PLANT AND MACHINERY.

In a recent report to London County Council the Finance Committee state that they have considered the question of the periods (25 and 20 years) allowed for repayment of loans for engineering plant and machinery.

The report states that the particular instance on which the question was first raised was in connection with the machinery at Abbey Mills pumping station. That machinery was not comparable with the electric lighting plant and machinery for which 20 years are sanctioned in loans to metropolitan borough councils. It would, however, be not unreasonable to draw a comparison between the plant and machinery at the Council's electric generating station at Greenwich and the larger corresponding items installed by borough councils at their generating stations. The basis on which the respective periods of 20 and 25 years have been settled is mainly the estimated life of the work. In the case of loans to borough councils the terms of repayment are fixed strictly on that basis, and the periods sanctioned for various parts of the same work differ according to their estimated life as reported by the Council's officers, and in the case of plant and machinery 20 years are almost invariably allowed. The period of 25 years was adopted by the Council with the sanction of H.M. Treasury in 1893, with a view to simplifying the accounts by charging over a single period expenditure the repayment of which was then being spread over terms varying from 15 to 50 years, and the term of 25 years then represented approximately the equated period of the amounts made repayable over those varying terms. The 25 years' period was introduced before the commencement of expenditure by the Council on tramways, and in recent years the great bulk of the expenditure of the Council which was spread over 25 years was incurred for that purpose. The application of the term of 25 years to tramway expenditure was specially considered when that expenditure arose, and H.M. Treasury concurred in the term, "having regard to the permanently remunerative character of the undertaking which is being purchased, and on the understanding that, in future, renewals will be charged to the revenue derivable from the tramways." The Treasury approved the period of 25 years also for the estimated cost of conversion from horse to electric traction, including the cost of equipment, "on condition that renewals of appliances and equipment were charged to revenue during the period allowed for the repayment of the primary outlay thereon."

It should be stated that "renewals," in the sense in which it was used by the Treasury, means not only renewals within the loan period, but also the supply of new plant and machinery, when necessary, after the expiration of the loan period.

It has been represented to us (proceeds the report) that these considerations apply precisely to any loan sanctioned by the Council for electricity purposes of the borough council, and that, speaking generally, the principle of some extended period for repayment is justified. In support of this it has been urged that electricity mains, at the beginning of an undertaking, are lightly loaded, that the machinery and plant are but little used, and that yet the undertaking has to bear at once the full debt charges, though its earning power is at first very limited. We would point out, however, that this has been met in the case of several borough councils by allowing them to postpone the commencement of repayment up to three years in respect of loans for the initial cost of electricity installations and for the initial cost of large extensions. During the period of postponement no charge falls on the undertaking for repayment, but only for interest on the borrowed money. The Council has not sought this relief in respect of any of its own expenditure on electrical machinery, and it appears to them that this argument does not affect the question of the period of repayment. Up to 1906 electric lighting loans were granted for an all-round term of 42 years, subject to the condition that if any renewal were necessary during the currency of the term the cost of such renewal should constitute a maintenance charge, and should not be made the subject of a fresh loan. Since the introduction of the 20 years' term that condition has been dropped, and borough councils are allowed to borrow for renewals or replacements, provided that any loan outstanding on the replaced plant is paid off. With one or two exceptions, none of the metropolitan borough councils which have borrowed for periods admittedly in excess of the life of the work, has provided a reserve fund for renewals calculated on a basis sufficient to provide new plant at the expiration of its probable life. The Council urges the borough councils to make provision for the renewal of electric lighting machinery by way of an adequate reserve fund for renewals, but it cannot insist upon such a fund being established and properly maintained, though up to the present the Council has not granted any loan for renewals, except where the original loan is wholly repaid. On the other hand, the Council does not borrow for replacements at all. In the case of the tramways a renewals fund has been established, which is calculated to provide the whole cost of any replacements. So far as the plant and machinery at Greenwich generating station are concerned, the tramways renewals fund ($\frac{3}{4}$d. per car-mile) is based on the following estimated lives: Machinery, &c., 25 years; boilers, &c., 20 years; sundry small items, 10 years. The 20 years' period allowed to borough councils covers all items of machinery, plant and boilers, and the initial cost of small items as well. The Council, further, repays the whole of its debt on plant and machinery, on the system of equal instalments of principal, and if the amount of the annual instalment of principal required to repay a given amount of debt in 25 years were set aside to a sinking fund to repay the debt on the annuity system, the amount of the debt would be provided at the end of 19 years; in other words, the repayment of the debt in 25 years on the instalment system is equivalent to repayment on the annuity system in 19 years. The borough councils can elect to repay their loans on either the instalment or the annuity system. The committee submit that if a borough

Digitized by Google

council elects to repay its debt on the annuity system, it is not badly treated compared with the Council if it has to repay in 20 years, whilst the Council repays on the instalment system in 25 years.

The representations which were made to the committee were not to challenge the propriety of the term of 25 years which the Council adopted for the repayment of its own expenditure, but to urge that the period of 20 years allowed to borough councils should be extended to 25 years; but the committee state that they are of opinion that, in the circumstances, the Council would not be justified in extending the period of repayment of loans of the borough councils beyond the estimated life of the works. The term of 20 years was the subject of very careful consideration, and was adopted on the advice of Prof. Sir Alex. Kennedy and the Council's chief engineer. Moreover, the term of 20 years allowed by the Council in sanctioning loans by borough councils compared favourably with the terms allowed by the L.G. Board for electrical machinery. The Board does not allow an equated period.

Having, therefore, carefully considered the whole matter, we have (says the committee) come to the conclusion that the borough councils are not hardly treated as compared with the Council's own position in regard to loans of the kind in question, but that, taking all things into consideration, the Council applies to its own undertaking a stricter rule than it is able to apply to the local undertakings. We are not prepared to recommend any modification of the present practice.

THE METALITE LAMP.

The future before the metal filament lamp in this country and the colonies should be a particularly rosy one. Central station engineers have got over the shock which they received at the time of the introduction of this form of lamp, and are now urging its use upon all their consumers. This action in itself will create an enormous demand, and with the co-operation of electrical contractors and allied trade houses there should be no difficulty in maintaining a brisk business in metal lamps for many years to come.

It is something of a consolation to find that British enterprise is well to the front in these matters. While we may have been slack in the early development of the metal lamp, we have made up a lot of leeway and should now be able to go ahead successfully. The Bryant Trading Synd., as our readers are well aware, has been associated with incandescent lamp making since the earliest days of electrical industry. They have been making metal filament lamps for a number of years, but have been anxious to perfect a type which would give every satisfaction to the public, who, after all, must be the best judges of the merits of electricity consuming devices of every description.

We were given a recent opportunity of inspecting the Horsell-road factory, where the British Metalite lamp is turned out in large quantities, and the works afforded ample testimony of the existence of a flourishing business. The productive equipment is the best that inventive genius and constructive skill can provide, and the girl operators—women seem peculiarly adapted for this class of work—are extremely deft in the carrying out of their delicate duties.

Special attention has been paid to the exhausting plant, including the latest pattern of rotary mercury pumps, which are used in connection with McLeod gauges and an auxiliary reciprocating vacuum pump. The process of mounting the filaments is also interesting. The ends of the filaments are severally welded by electrical means to the radial supports projecting from the lower part of the lamp stem, the looped ends of the filaments resting upon specially shaped springs.

While the actual manufacture of complete lamps at Horsell-road is an important section of the company's operations, an extensive business in metal filaments is being conducted. These filaments are prepared in large quantities and exported to all parts of the world. Extreme care is taken in the packing and the methods adopted for different sizes of filament have, we understand, proved extremely satisfactory. We are informed that, despite a 45 per cent. tariff, a tremendous business in the supply of Metalite filaments to the United States of America is being carried on. This in itself is a mark of appreciation of which the company may well be proud.

It is claimed for the Metalite lamp that it has an average light duration of 2,000 hours, that it will successfully resist vibration, and that with an 8 c.p. lamp 40 hours illumination can be provided at a cost of a penny. We were shown some 200 volt 25 c.p. lamps in ordinary pear-shaped bulbs which looked very businesslike, and which we understand are turned out in very large quantities.

P.O. Telegraphs Flower Show.—The Postmaster-General, Mr. Herbt. Samuel, and Mrs. Samuel (who awarded the prizes) on Wednesday visited the Central Telegraph Office Amateur Gardening Association's exhibition at St. Martin's-le-Grand, London. The controller of telegraphs (Mr. J. Newlands) and the deputy controller (Mr. J. Willshire) were also present. The exhibits included cacti, roses, sweet peas, violas and vegetables.

LEGAL INTELLIGENCE.

Attorney-General (ex rel. India Rubber, Gutta Percha & Telegraph Works Co.) v. West Ham Corporation.

Mr. Justice Neville continued the hearing of this action in the High Court since our last report.

At the close of plaintiffs' evidence, Mr. MacMorran summed up the case for plaintiffs. He said the electricity undertaking of the Corporation was a separate trading concern, and that being so the Corporation were required to keep and publish separate accounts in respect of it. It had been proved that the Corporation had overdrawn both the capital and revenue accounts. On the face of it, therefore, there was something that called for an explanation. He found that the overdraft both of capital and revenue was not covered by any sanction to borrow or any statutory authority.

His LORDSHIP: With regard to the electricity supply there was not.

Mr. MACMORRAN said they had to proceed upon that state of things. The Corporation kept separate accounts of their different undertakings, and the result as regards the electricity account was as he had stated. It had been suggested that there might be some power to borrow with regard to the capital account, but it could not be suggested with regard to the revenue account, for these the Corporation had to provide for the expenses out of the district rate. It could not be said that there was a sanction for this overdraft because there was enough money to meet it out of the general district rate, for the money had not been so applied. The money was represented by motors, fittings, &c. In other words, they had borrowed money from the bank to buy motors and fittings, and by doing so they had contracted an illegal debt.

Mr. Justice NEVILLE: Assume the borrowing for electricity was ultra vires, you had to consider what was the result. You could not restrain them borrowing without the sanction of the L.G. Board that which was already borrowed. He supposed all that could be done was to restrain further borrowing.

Mr. MACMORRAN said if it was an illegal borrowing then it was an illegal debt. It was not merely ultra vires, but it was a thing that was illegal for them to do. That being so, the Corporation had no power to apply any money in their hands for payment of such a debt.

Mr. Justice NEVILLE: But supposing they had done it.

Mr. MACMORRAN submitted that in that case they would have to repay. It might have to go further and make some persons personally responsible. With regard to the interest on the money there could be no question that if it was borrowed without express sanction the interest ought not to be paid.

Mr. Justice NEVILLE: Assuming you are entitled to an injunction, what do you say as to the rest of the relief?

Mr. MACMORRAN said that if originally illegal no subsequent act in paying off the money could legalise it.

Mr. Justice NEVILLE said he saw some difficulty in the form any order ought to take. The only way the Corporation could put themselves right was by levying a rate for the purpose, and he was not sure that they could legally levy a rate.

Mr. MACMORRAN pointed out that the Corporation had sources of revenue other than the rates. It was sufficient for plaintiffs that the debt was illegally incurred, whatever the consequences might be that followed from it. He submitted that the money must be put back somehow. If the bank gave that loan with the knowledge that it was illegal, then the bank was liable. From the way the accounts had been kept it was clear that the bank had had notice that there was a large overdraft in respect of the electricity account.

On Friday Mr. DANCKWERTS opened the case for the defendant Corporation. He submitted that the case was founded upon mere technicalities, and the Attorney-General had disregarded the substance of things. Plaintiffs' accountant had admitted that there had been nothing in the nature of dishonest dealings and the overdraft at the bank had been treated by the drawing of cheques in favour of the lawful creditors of the Corporation. What had really happened was that by arrangement the Corporation had got the bank to pay its creditors. They had done nothing more than for the sake of convenience to transfer the debt from one creditor to another, and that, he submitted, they were perfectly entitled to do. The Corporation were advised that during the period under discussion—the period during which this overdraft was created—it would be inexpedient to go to the stock markets to raise money. They suffered in that respect and also in consequence of the extraordinary delay on the part of the L.G. Board in giving their sanction for raising certain loans. Under those circumstances what was the Corporation to do? Their affairs could not be allowed to stand still and creditors had to be paid. The only practical thing for them to do was to go to the bank and get them to pay the creditors. With regard to the Consolidated Loans Fund, he submitted the Corporation had the right to lend themselves the money pending the sanction they were expecting to get from the L.G. Board daily or even hourly. He should ask the Court to say that the Corporation in no way deserved castigation, and that technicalities could be pressed too far. No harm had been done. The action was supposed to be taken in the interests of the ratepayers, but it would have just the reverse result, as that action was unnecessary and expensive, and had been started by people who could not hope to benefit by it.

Mr. PATTERSON, borough treasurer, answering Mr. Danckwerts, gave details of the method of keeping the Corporation's accounts and the application of the overdraft.

Digitized by Google

In cross-examination by Sir ALFRED CRIPPS, he said that in 1906 the authorised loan was £94,026. It was true that at that time they were negotiating with the bank for borrowing £200,000, and that was partly for the electricity and partly for the education account. When the letter was written to the bank on Jan. 23, 1906, the total sanction obtained for loans amounted to £94,026. They had no other sanction, but they had borrowing powers outside the sanctions. The Board of Education required £26,093. Their borrowing powers were not exhausted at that time. Of the money the Corporation was then getting from the bank, part was spent on electricity supply, but witness did not know the exact amount they set off against the general district fund which was overdrawn on the electricity account. There was always a substantial working balance left over from the district rate. It was looked upon as a working balance for the whole of the accounts of the Corporation. For the year ended March 31, 1909, the estimated charge on the district fund for the electrical undertaking worked out at £116,669 odd. The Corporation had included in the general rates sums for the payment off of the overdraft.

Do you think it is right for any purpose to mix up the district fund account with the borough fund account?—Theoretically no, practically yes. Properly they could not have taken any part of the borough fund for electrical purposes. In March, 1910, the overdraft for electricity supply was: revenue account £35,000 odd, capital account £57,000 odd. Substantially, since 1903 up to 1907 the rates had been 10s. in the £. He denied that their real difficulty in raising money was that their rates were so high. They were paying the bank 4 per cent. for the borrowed money, and they were crediting the loan account with 4 per cent. The interest on the consolidated loan fund was 1½ per cent. below bank rate, at that time the bank rate was 3 per cent., so that they were paying on the consolidated loan fund 1½ up to March, 1908. He did not know that the relators in that case were paying £7,000 a year in rates, but he knew that they were very large ratepayers.

This concluded the evidence for the Corporation, and Mr. BUCKMASTER, K.C., opened the case for the bank. He said the money obtained from them had been used for the purpose of keeping the electrical undertaking going, and it was in evidence that the electrical undertaking could not have gone on without that money being raised. There was no evidence that the bank knew the way the money was being expended. The statement to the bank was that it was necessary to keep things on foot, to pay the people who had done the work and the people who had supplied the goods. Either the Corporation had to pay these expenses or the creditors had to go unpaid. He submitted that these were debts legally incurred for a lawful undertaking. The debt to the bank was incurred by the Corporation for its authorised undertaking, and was honestly incurred in pursuance of a lawful undertaking. It was necessary for the continuance of the undertaking that the creditors should be paid, and to the bank whose money had paid them the money must be refunded. It could not be right that the ratepayers should enjoy this undertaking financed by the money of the bank, and then leave the bank unpaid. In conclusion, he contended that all the bank had done was to lend a sum for which they knew the Corporation had borrowing powers, and they could not be held responsible if the Corporation had applied the monies for purposes for which they had no borrowing powers.

Sir ALFRED CRIPPS replied on the whole case. He said that he had consulted with Mr. Buckmaster, and for the present was willing to leave the case against the bank where it was. His lordship would understand that what plaintiffs were anxious for was a declaration that the course of conduct of the Corporation was ultra vires.

In the course of the reply terms were arranged as regards the bank. It was agreed that upon payment by the bank to the Corporation of £7,000 in respect of the interest paid to the bank on the balance of the overdraft, and on the bank agreeing to pay plaintiffs' costs as between party and party, including the indemnity costs, all proceedings against the bank should be stayed. The £7,000 was to be paid to the credit of the Corporation at once.

Mr. BUCKMASTER desired to point out that, though the bank had come to that agreement for the purpose of saving embarrassing inquiries, they in no way admitted any liability.

At the conclusion of the reply his lordship reserved judgment.

Reid Newfoundland Co. v. Anglo-American Telegraph Co.

On Friday the Judicial Committee of the Privy Council delivered their reserved judgment in this appeal from a judgment of the Supreme Court of Newfoundland.

Lord MACNAGHTEN, in delivering judgment, said the Supreme Court had restrained appellants (the railway company) from erecting, maintaining or operating a line of telegraph upon their own land for the efficient working of their own railway. The result depended on the construction of an agreement of Aug. 11, 1888, made between the Newfoundland Railway Co., its receiver and manager and the Anglo-American Telegraph Co. By that contract the railway company agreed that the telegraph company should have (for 27½ years from November 1, 1888) the exclusive right to build, erect, maintain and operate upon and along the lands forming the roadways of the southern division of the railway company's line between St. John's and Harbour Grace and between Harbour Grace and Carbonear, as many telegraph lines for the business of the telegraph company as the telegraph company might deem necessary, and a special wire for the use of the railway company (their servants and agents, and successors and assigns) for use in the management, operation and control of their railway, with all necessary posts, wires, &c. By another clause in the agreement the railway company agreed not to transmit commercial messages over the special wire, except for the benefit and account of the telegraph company; and the telegraph company agreed to build and erect with good and suitable materials, &c., and to maintain in good working order and operate at least two lines of telegraph wire from the railway station at Harbour Grace to the railway station at Carbonear, one of such wires to be for the use of the telegraph company, the other to be a wire (called the "special wire") for the special and exclusive use of the railway company. The contract was one between a railway company seeking its profits by serving the public as railway managers and concerned with telegraphs so far as necessary for the safety of the railway and the efficiency of its working, and on the other hand a telegraph company seeking its profits by supplying telegraphic convenience to the public. The question that arose in the former case between the parties was as to the extent of the right of the railway company to use the special wire provided for its use, whether that use was limited to the purposes of the railway as it existed in 1888 (the date of the contract) or whether it extended to the purposes of the railway as afterwards developed.

On that occasion the view of the Court in the Colony was affirmed, and it was held that the right of using the wire was limited to the purposes of the railway as it existed at the date of the contract. That decision appeared to have been felt by the railway company as placing it in a difficulty, and it proposed to meet that difficulty in a way which had given rise to the present litigation. The railway company proposed to lay telegraph lines of their own along their own lands for working their railway. That was what was objected to by plaintiffs in the present suit, and that objection prevailed in the Court of the Colony. Their Lordships had to say whether that objection was well founded. The argument on behalf of the telegraph company was largely based upon the use of the words "exclusive right" in the clause cited. It was necessary, therefore, to see what the "exclusive right" referred to was. It was not an "exclusive right" of entry, for the railway company remained in possession, and must do so in order to work its railway, which it was under an obligation to do. The exclusive right granted was to enter for the purpose of erecting, maintaining and operating telegraph lines for the business of the telegraph company. In their Lordships' opinion that exclusive privilege of erecting and working telegraph lines for the business of the telegraph company did not exclude the right of the railway company to erect and work telegraph lines on its own property for the purposes of its railway business. Their Lordships were of opinion that the railway company was not shown to have exceeded its rights. They would humbly advise his Majesty that the judgment and decree of the Colonial Court should be set aside, and the suit dismissed with costs in the Court below. Respondents would pay the costs of the appeal.

G. Freeman & Sons v. Middleton Electric Traction Co. (Ltd.)

At Manchester Assizes last week Mr. Justice Hamilton tried an action for the recovery from defendant company of sums amounting in the aggregate to £1,699, in respect of extra work done in connection with the construction of a tramway from Rochdale through Castleton to Middleton.

For plaintiffs it was stated that they obtained from defendants the tender for the construction of the tramway for £38,761 in 1901. It was agreed that payment was to be made for certain extra work not contemplated in the contract. In due time the work was completed, and the final certificate of the engineer (Mr. Stephen Sellon) was given. The Middleton Electric Traction Co. was a subsidiary company of the British Electric Traction Co. A Mr. Angus, who had since died, was appointed resident engineer in the case of the Middleton and Rochdale tramway, and in that capacity had given orders for extras, and it was in regard to these orders that the action arose. The total amount of the extras ordered was stated to be £6,843.

Defendants pleaded that Mr. Angus was not authorised, within the meaning of the contract between the parties, to give orders, and they also claimed that some of the work in respect of which the action arose was work contemplated in the original contract. They admitted that they had declined to submit the case to arbitration.

Mr. SELLON, in the course of his evidence, said that during the construction of the tramway he had been on the job some 20 or 30 times, and he did not sanction the appointment of Mr. Angus as resident engineer.

In giving judgment, his LORDSHIP said Mr. Angus was never anything but a resident engineer, the deputy of Mr. Sellon appointed to assist him, and not to relieve him of any of his duties under the contract. There was no evidence to satisfy him that Mr. Angus was the engineer to give orders in writing under the clause of the agreement which dealt with those matters. He therefore gave judgment for defendants. He did not think plaintiffs had been very well treated, but he had come to the conclusion that if he said judgment would be without costs it would only be because he was sorry for plaintiffs. That seemed to be an insufficient judicial reason, and therefore he gave defendants their costs. He refused to grant a stay of execution.

Collins v. Bradford Corporation.

At the West Riding Assizes (Leeds) on Tuesday, before Mr. Justice Grantham and a special jury, a carter named Mark Collins sought to recover damages from Bradford Corporation owing to the alleged negligence of defendants' servants. The claim arose out of a tramcar accident in Leeds-road, Bradford, on Sept. 15, 1909. Plaintiff was taking a cartload of bricks down the street when he saw a tramcar coming at high speed. As there was another cart in front of him, he could not pull to the left, so he whipped his horse and directed the cart to the right in an effort to avoid an accident. The tramcar, however, caught the cart, and threw him into the road.

Medical evidence was called to say that Collins would never be able to work again.

Digitized by Google

The defence was that the finger of the controller had become electrically fused, that that was an unusual accident, for which the Corporation could not be held responsible, and that plaintiff was guilty of contributory negligence.

Mr. C. J. SPENCER, manager of Bradford tramways, said he had never before known a controller stick in the way that did. Undoubtedly it was due to fusing, but what caused that he was unable to say.

After hearing the evidence the jury returned a verdict for plaintiffs for £350, for which judgment was given with costs.

Factory Act Prosecution.

At Houghton-le-Spring on Thursday last week the Newcastle-upon-Tyne Electric Supply Co. was summoned on two charges under the Factory and Workshops Act.

Mr. H. S. Mundahl appeared for the prosecution and Mr. W. S. Burton represented the company.

Mr. BURTON took a preliminary objection that the particular summons with which they were concerned did not disclose an offence.

Mr. MUNDAHL replied that the information was that a certain man died by reason of defendant company having neglected to observe the regulations made in pursuance of the act by permitting an unskilled man, not being an authorised or competent man, to undertake certain work.

Mr. BURTON said that the particular summons did not set up an offence, and was most misleading.

Mr. MUNDAHL said defendant company was the owner of works for generating, transforming and distributing electricity at Philadelphia, and on April 15 they had occasion to employ a joiner (Liddell) in a kind of passage between the switchboard and wall of the works building. There was about 3 ft. between the wall and the board, and on the morning in question Liddell went with an electrical engineer named Archbold to do something in connection with the conductors. Archbold was to refit a bush which had got loose, and for which Liddell had made a wedge. By some means Liddell came in contact with one or other of three conductors, and received a shock of about 3,000 volts, with the result that he was killed. There could be no doubt that Liddell met his death while he was engaged at work at the back of the switchboard, and that he was killed by an electric shock in consequence of coming into contact with some of the conductors conveying electricity at a very high pressure. Mr. Mundahl urged that Liddell was not a man of technical knowledge or experience as was adequate to avoid danger. Liddell was employed by Mr. Wardroper, and was permitted by the company or their officials to go into the place referred to, and to be exposed to danger where practical knowledge or experience was required in order to avoid danger. It might be that Liddell was handing something to the electrician—they did not know exactly what had happened; but what the prosecution urged was that deceased was permitted to engage in work where technical knowledge or experience was required to avoid danger. It might be said that the conductors were insulated, and that certain precautions were taken to render them as harmless as possible; but, insulation or not, the man was killed, and he submitted that an offence had been committed by defendants having failed to take adequate steps to prevent deceased from engaging in the work referred to.

Mr. BURTON: My point is that Liddell was a competent joiner, was 31 years of age, a man with full possession of his faculties, and, to that extent, on April 15, he was electrically competent, and therefore filled all the requirements of the act. He contended that deceased was electrically competent by knowledge imparted to him by persons at the works and warnings given him.

Mr. MUNDAHL said the only question for the bench was: Was the deceased competent, a competent man where technical knowledge or experience was required in order to adequately avoid danger.

Mr. BURTON said it was for the prosecution to show that the man was not competent. That had not been proved, and, therefore, prima facie, the prosecution had not made out a case in respect of that summons.

Mr. GEO. WARDROPER, contractor, Penshaw, said deceased was a competent man as a joiner, and had been employed at the Philadelphia power station for three weeks.

Mr. F. F. PYLE, engineer-in-charge of the station, said Liddell had to get permission from witness before he could work at the western switch chamber where the fatality occurred. The "passage" was not exactly a passage, but was the inside of the chamber. One-half the chamber was occupied by the switchboard. Liddell was under the charge of Archbold. Liddell was doing work in the western chamber similar to what he had done in the eastern chamber, the chambers being alike. Witness told Liddell he must not touch the insulated conductors. The conductors were distinctly painted yellow. Witness told deceased that they were "alive," and that a cut of a chisel or any sharp tool might cut through the insulation.

Mr. P. H. ARCHBOLD, with whom deceased was working, said Liddell handed him a wedge to complete a job.

Mr. MUNDAHL: You thought it necessary that this man should be warned?—Yes.

Unless he was warned there was danger?—Yes.

If he had the technical experience and knowledge of a competent man, why was it necessary to warn him?—He might have forgotten.

Mr. MUNDAHL: The warning suggests that the man had no knowledge.

Mr. BURTON: My friend puts it to you (witness) that there was danger. I suggest it was nothing more than a risk, and that apparently the insulation was sound?—That is so.

Mr. J. CUSWORTH, chief engineer of the operative department of the Newcastle Electricity Supply Co., said the switchboard was of the latest type, and the insulation of the conductors the best that could be used. All that Liddell required to know was that the conductors were alive, and that there was risk if he came in contact with them with tools. If they were unable to employ a joiner in such circumstances as Liddell was employed there would be unreasonable and serious interference with their business, as they supplied collieries with electricity night and day.

Mr. BURTON asked the bench to find, in the first place, that Liddell was competent, and that, in the second place, the company had done all that was reasonably necessary to provide against the man meeting with any sort of accident. He submitted the company was clearly justified in employing Liddell, having regard to all the circumstances.

The bench consulted, and the chairman (Mr. R. Richardson) said the magistrates found that the man was not competent for the work he had to do, and they, therefore, fined the company £10 and costs.

Mr. MUNDAHL said they had brought the case to get a definition of the word "competent" for the public benefit, and did not ask for costs.

Mr. BURTON said he might be instructed to take the decision to a higher court, and the magistrates thereupon, in the event of an appeal, fixed the recognisances at £100.

Mr. MUNDAHL said he would not proceed with the second summons.

Metropolitan Rly. Co. v. G.W. Rly. Cy.

On Wednesday the Railway and Canal Commissioners (Mr. Justice A. T. Lawrence, Mr. Gathorne-Hardy and Sir J. Woodhouse) sat to hear a dispute between the Metropolitan and Great Western Railway Co.s as to the basis on which the latter were to pay the former for adapting their line for electric traction.

Mr. Balfour Browne, K.C., and Mr. G. A. Thomas appeared for the Metropolitan Railway Co., and Sir A. Cripps, K.C., Mr. Simon, K.C., and Mr. W. S. Kennedy represented the G.W. Railway Co.

Mr. BALFOUR BROWNE said the G.W. Co. had running powers over the Metropolitan Co.'s system from Bishop's-road to the City, and paid a minimum of £15,000 a year for the privilege. In 1893 the Metropolitan Co. obtained an act empowering them to substitute electric for steam traction. It was provided that if the company should at any time require the Great Western Co. to substitute electric traction for steam locomotives for working their trains over the system of the Metropolitan Railway Co. the question as to how the cost, or any part of it, should be borne should be referred to arbitration. The Metropolitan Co. gave the Great Western Co. notice to substitute electric traction for steam locomotives, and by agreement the Metropolitan Co. supplied the necessary electric traction. The question for the court was as to the amount of the remuneration the Metropolitan Co. were to receive for those services. He submitted that they should receive the actual cost of supplying the traction, with a reasonable sum for profit.

Sir A. CRIPPS, for the G.W. Co., contended that the question which had to be referred to arbitration was not the cost incurred by the Metropolitan Co., but the cost thrown on the G.W. Co. by the demand of the former. The payment, he said, should be based on the actual saving of cost to the G.W. Co. That company could not be called upon to bear a greater cost in connection with electric traction than they had originally undertaken in connection with steam locomotion.

The court held that the arbitration clause of the Act of 1898 was passed for the protection of the G.W. Co., and that the cost to be borne by that company was on the basis of the cost they were put to for steam traction.

It was arranged that counsel should agree to the form in which the decision of the court should be drawn up and submit it to the court.

Witney Electric Supply Co. (Ltd.)—On Friday Mr. Justice Swinfen Eady made an order for the appointment of a receiver of this company, which was formed in 1899; in 1902 they created an issue of debentures. The interest was not in arrear, but the case was one of jeopardy (said counsel). The company was being carried on at a loss, and would not be able to pay the interest in December or to pay off the debentures that fell due in December.

PARLIAMENTARY INTELLIGENCE.

LEEDS CORPORATION BILL.

Last week the Committee on Unopposed Bills in the House of Commons considered this bill, which had already been through the House of Lords.

Mr. PRITCHARD, parliamentary agent, explained that the bill authorised the provision of omnibuses worked by electricity, and to carry out street improvements, &c. The vehicles it was proposed to run were trolley vehicles or trackless trams.

Mr. J. B. HAMILTON, general manager of the Leeds tramway undertaking, explained that the cars would be run on pretty much the same principle as ordinary trams, the difference being that the return current, instead of going through the rails would have to return by duplicate overhead wires. Those cars were successfully running on the Continent. The capital charge was about one-fifth of the ordinary trams, but the cost of working was much the same. They were very much lighter vehicles, and were intended for sparsely-populated districts. Where there were large centres of population it would be much preferable to have ordinary tramways. But these would serve sparsely-populated and distant parts of the city, whence they had had application for some means of communication, and where, because of the heavy initial cost, they had been unable to consider the question of ordinary tramcars. If those districts developed and there was sufficient traffic eventually for tramways, then

Digitized by Google

the trolleys and wires would be utilised without alteration, but they would have to lay down lines.

Mr. PRITCHARD explained that in the Bradford bill the Corporation was taking practically similar powers with regard to trackless cars, and the Local Legislation committee which had considered the bill had agreed to the Board of Trade having power by Provisional Order to authorise additional routes or variation of the routes sanctioned in the bill if that became necessary. Leeds had followed the same course. It was so also with regard to the period of repayment. Leeds had in their bill originally 10 years for vehicles and 20 for equipment, but the Local Legislation committee said 15 years for both. So Leeds, while thinking their own proposals best, adopted those put into the Bradford bill.

The CHAIRMAN said he was of opinion that 10 years and 20 years was much sounder finance, and the committee agreed.

The bill was then ordered to be reported for third reading.

WIRELESS TELEGRAPHY AND THE COLONIES.

In the House of Commons on Wednesday Mr. SANDYS asked the Under-Secretary for the Colonies whether the recommendations of the conference, held in Melbourne in December, upon the establishment of wireless telegraphy between Australia, New Zealand, and the Pacific Islands, had been adopted by the Governments concerned.

In reply, COLONEL SEELY said he understood that the Australian and New Zealand Governments had taken steps to establish high power stations at Sydney and Doubtless Bay, but it had not yet been possible to carry out the recommendations of the conference with regard to the Pacific Islands. Of course they expected to hear from them when the work was completed or nearing completion; but the time had not yet come for a statement of that kind.

Mr. GIBSON BOWLES asked, in view of the great importance of an increase in those wireless telegraph stations in that hemisphere, whether the Government would do their best to secure the establishment there of as many stations as they could.

COLONEL SEELY said he could not give a pledge as to that. Of course it would be of great value, but he was afraid he could not make a statement now.

MUNICIPAL, FOREIGN & GENERAL NOTES.

APPOINTMENTS VACANT AND FILLED.

A sub-station attendant is required for the Stepney (London) electricity supply department. Applicants must have had experience with h.-t. three-phase a.-c. switchgear, converting plant and l.-t. three-wire d.-c. supply. Commencing salary 30s. Applications to the engineer and manager (Mr. W. C. P. Tapper), 27, Osborn-street, Whitechapel, E. See advertisement.

The governing body of the Northampton Polytechnic Institute London, invite early applications for the appointments of senior assistant in the electrical engineering department, to take charge of new electric generating station (salary 45s. per week); junior assistant in electrical engineering department, chiefly to take charge of producer plant (28s. per week); second lecture assistant in electrical engineering department (£80 per annum); and assistant lecturer and demonstrator in the mechanical engineering department (£120 per annum). The appointments will take effect after the summer vacation. Particulars from the office of the Institute or from the principal, Dr. R. Mullineux Walmsley. See advertisement.

Applications are invited for the positions of assistant in the mechanical and electrical engineering department of the Municipal Technical School, Halifax (at a commencing salary of £160 per annum), and lecturer in mathematics (specialist in practical mathematics), at a commencing salary of £150 per annum. Forms of application (to be returnednot later than July 28) from the Secretary of the Education Offices, Mr. W. H. Ostler, Halifax.

There is a vacancy in the civil and mechanical engineering department of the City and Guilds Central Technical College for an assistant who has had drawing office and workshop experience, and who has had sufficient college training to enable him to lecture in the subjects of "Strength of Materials," "Mechanism" and "Heat Engines." Commencing salary £150 a year. Applications to the Dean of the College, Exhibition-road, London, S.W. See advertisement.

An assistant lecturer in engineering is required at the Technical College, Derby. Commencing salarg £140. Particulars from the Registrar.

Applications will be received until Sept. 10 for appointment to the Henry Overton Wills Chair of Physics at Bristol University. Salary £600 per annum. Particulars from the Registrar.

A lecturer in technical engineering is required at Blackburn Municipal Technical School. Salary £120 to £140. Forms from the Director of Education. Applications by Aug. 13.

A Canadian publishing house advertise for an experienced editor for an electrical journal.

Bombay Corporation require an executive engineer with knowledge of all branches of municipal engineering, including lighting and electricity. Minimum monthly salary R.1,200 (£80), maximum R. 2,000 (£133. 6s. 8d.). Applications to Mr. G. Midgley Taylor, Caxton House, Westminster, S.W., by July 31.

Dr. W. Geoffrey Duffield, of Manchester University, has been appointed professor of physics at University College, Reading, in succession to Prof. G. J. Burch, M.A., D.Sc., resigned.

Mr. W. J. McDonald, late traffic superintendent of Colchester Corporation tramways, has been appointed traffic superintendent on the Burton & Ashby Light Railway.

Mr. H. P. J. Moseley, B.A., has been appointed lecturer and demonstrator in physics at the Victoria University, Manchester.

EDUCATIONAL NOTICES.

City and Guilds of London Institute.—The entrance examinations of the City and Guilds Central Technical College, Exhibition-road, S.W., and the City and Guilds Technical College, Finsbury, E.C., are held in September, and the sessions commence in October.

Both institutions provide courses of instruction in engineering, chemistry, mechanics and mathematics, &c. Particulars of entrance examinations, scholarships and courses of study may be obtained from the respective colleges or at the head offices of the Institute, Gresham College, Basinghall-street, London, E.C. The Central Technical College is intended for higher technical instruction for day students not under 16 years of age, preparing to become civil, mechanical or electrical engineers, chemical or other manufacturers and teachers. The college is a school of the University of London, and forms the engineering section of the Imperial College of Science. The courses of the study for the associateship of the Institute cover a period of three years.

The City and Guilds Technical College at Finsbury (London, E.C.) is designed for day students preparing to enter engineering and chemical industries and for those who have already served an apprenticeship and also for evening students. The day courses in mechanical or electrical engineering cover two years and those in chemistry three years.

A petition has been presented to His Majesty in Council by the City and Guilds of London Institute for the grant of a supplemental charter, and His Majesty has referred the petition to a committee of the Lords of the Council. All petitions for or against such grant should be sent to the Privy Council offices by July 30.

Northampton Polytechnic Institute (London).—Full day courses in the theory and practice of mechanical and electrical engineering and electro-chemistry will commence on Monday, Oct. 3.

The courses in mechanical engineering include specialisation in automobile and aeronautical engineering, and those in electrical engineering include specialisation in radio-telegraphy. The entrance examination takes place on Sept. 28 and 29. Three entrance scholarships of the value of £52 each will be offered for competition at the entrance examination. The courses include periods spent in commercial workshops and extend over four years. They also prepare for the degree of B.Sc. in engineering at the University of London. There are full and part time courses in all branches of technical optics. Particulars as to fees, &c., can be obtained at the Institute, Clerkenwell, E.C., or on application to the principal, Dr. R. Mullineux Walmsley.

University of Manchester.—The session commences on Oct. 4. Complete theoretical and practical training is given in this university to students preparing for the higher positions in the electrical engineering profession. The subject may be taken as part of the courses preparing for the B.Sc. degree in both the honours schools of engineering and physics. The John Hopkinson laboratories and dynamo house are well equipped, and offer good facilities for educational and research work. Prospectuses from the Registrar.

Armstrong College, Newcastle-on-Tyne.—The next session commences on Sept. 26. The matriculation examination takes place on Sept. 20-23. There are full courses of instruction in mechanical, marine, civil and electrical engineering, naval architecture, mining, metallurgy, agriculture, pure science, arts and letters. Particulars from the secretary, Mr. F. H. Pruen, M.A., Armstrong College, Newcastle-on-Tyne.

BRITISH AND COLONIAL.

Ashburton.—The Council will oppose an application for a provisional order by Purvis & Co.

Ashford.—The East Kent Electric Supply Co. will apply for a provisional order.

Ashton-under-Lyne.—The Council propose to expend £48,424 in extensions of the electricity undertaking.

Atherton.—The South Lancashire Tramways Co. has authorised the Council to use the tramway poles of the company for attaching overhead cables for the supply of electrical energy to consumers over the Atherton boundary in Bolton-road.

Digitized by Google

Assessment of Tramways.—At the annual conference of Urban District Councils of England and Wales last week at Ilfracombe, the following resolution was adopted on the motion of Mr. W. Wood (clerk to Fleetwood Council):—

That in view of the unsatisfactory state of the law with regard to the assessment of street tramways, whereby the anomaly is presented of a tramway assessable to the general district rate at its full net value, and of an undertaking similar in construction and use, but constructed under the provisions of the Light Railways Acts, being only assessable at one-fourth of such value, this conference urges upon the Local Government Board the necessity for a Government bill being introduced at the earliest possible date providing for the assessment of all tramways or railways running through or along the public streets at their full net annual value for the purpose of all local rates.

Belfast.—The Corporation have adopted a report of the Tramways and Electricity committee, which recommended that powers be sought for the construction of eight additional tramway lines, &c., at a cost of £161,000.

Bradford-on-Avon.—The Western Electric Distributing Corpn. propose to apply for a provisional electric lighting order.

Dundalk.—The electrical adviser to the Board of Trade (Mr. A. P. Trotter) held an inquiry last week into the objections made to the electricity supply scheme of the Urban Council.

Mr. T. M. Healy, K.C., appeared in support of the scheme, Mr. Matheson, K.C., opposed on behalf of the Dundalk Gas Co., and Mr. Donaldson opposed on behalf of some ratepayers.

The objections to the scheme were that it provided for 9 miles of overhead wires, which crossed the strets at intervals, "to the danger of the public." There would be underground cables placed direct in the soil in the main thoroughfares, and it was contended that, owing to the nature of the soil, the gas pipes in nearly all the streets of the town would suffer from corrosion, and that if the electricity escaped it would set up electrolysis, to the detriment of the Gas Co. For the Council it was urged that they had adopted the specification of the Board of Trade, and that similar schemes were in operation elsewhere.

Edinburgh.—The Tramway committee have been asked to report on a communication received from the solicitors to a London syndicate who propose to obtain powers for constructing new electric tramways.

It was reported at a meeting of the Electric Light committee on Tuesday that the actual surplus for the year was £8,263, against an estimate of £2,020. It was agreed to defer proposals for the disposal of the surplus until they had reports from the engineers as to what the undertaking required. The convener (Judge Stevenson) proposed to alter the price of current, but it was agreed to adhere to the present price.

Exeter.—On Wednesday the Council decided on the recommendation of the Electric Lighting committee, to reduce the charge for electricity for power and heating by ½d. per unit and for traction by ¼d.

Falmouth.—The question of the acquisition of the local electricity works by the Council is to be considered.

Hackney (London).—The Electricity committee have decided to extend the feed and distributing system at a total cost of £18,364, and to extend the switchboard at a cost of £900.

The cables will be purchased under a current contract with the British Insulated & Helsby Cables, but tenders are to be invited for the switchboard.

The committee report that there is now so much practical heating and cooking apparatus on the market that it is worth while to cater strenuously for domestic heating and cooking business, and in order to stimulate this branch the committee have decided to modify the tariff, from Sept. 1 next, so that all supplies of current for domestic purposes other than lighting shall be supplied at 1d. per unit. A modified maximum demand system is to be tried, similar to that employed in Marylebone and Hampstead, and under this the following optional rate for supply of energy for lighting and other domestic purposes in premises which are lit solely by electricity is to be adopted: £2 per kw., equal to using electricity at the rate of 1 unit per hour and would give an illumination of 800 c.p. from metal filament lamps equal to 25 32-c.p. lamps per quarter, based on the rate at which the consumer desires to use the supply, payable quarterly in advance, and a charge for electrical energy used each quarter of 1d. per unit, with a discount at the rate of 10 per cent. of the rent to consumers who pay four quarters' rent in advance.

The mains are to be extended to Lingwood-road, Stamford-hill, and the showroom and offices at 306, Mare-street, are to be fitted up at an estimated cost of £550.

Hampstead (London).—An exhibition of heating and other electrical appliances is to be held in the Baths (Finchley-road) from Oct. 4 to 8 inclusive.

The Lighting committee have been authorised to convert 802 more gas lamps to incandescent electric lamps in addition to those already in hand.

Heston and Isleworth.—An inquiry was held here on Tuesday into the Council's application for a loan of £3,600 for extensions of the electricity supply undertaking

Japan-British Exhibition Awards.—The following awards have been made to exhibitors:—

Grand Prize.—Sir W. G. Armstrong, Whitworth & Co. (ordnance and machine tools); Vickers, Sons & Maxim (ordnance and naval models); Babcock & Wilcox (coal conveying plant); Thames Ironworks, Shipbuilding & Engineering Co. (collective exhibit); C. A. Parsons & Co. (steam turbines); Central London Railway Co. (working models); Dowsing Radiant Heat Co. (medical baths and heating appliances); Electromotors Limited (balancer set, motors, &c.); India Rubber, Gutta Percha & Telegraph Works Co. (telegraph apparatus and rubber goods); Osram Lamp Works (metal filament lamps and fittings); Western Electric Co. (telephones and cables); Chloride Electrical Storage Co. (cells and accessories); Brunner, Mond & Co. (pure alkali, &c.); United Alkali Co. (collective exhibit); Johnson, Matthey & Co. (collective exhibit).

Diploma of Honour.—Newtons Limited (d.c. generators and motors.

Gold Medal.—Hurst, Nelson & Co. (tramway rolling stock); John Thompson (dish-end boilers); W. R. Sykes' Interlocking Signal Co. (models of automatic signalling apparatus); Hans Renold Limited (steel driving chains); J. Hopkinson & Co. (safety boiler mountings and valves); E. Green & Son (fuel economiser); John Dugdill & Co. (moving and extending fittings); Maxim Lamp Works (flame and enclosed arc and metal filament lamps); Bertram Thomas (electric cooking appliances); Float Electric Co. (mining and small batteries.

Silver Medal.—T. & J. Jackson & Co. and Lambie, Wrigley & Co.

Leicester.—The Corporation have instructed Mr. James Swinburne to prepare a report upon the position of the electricity department and particularly as to the desirability of putting the Aylestone and Belgrave generating stations under one management.

London County Council.—On Tuesday it was agreed to sanction loans of £9,863 to Battersea and of £9,625 to Stepney for electricity purposes.

Invention.—Mr. A. Champion, an assistant in the electrical branch of the chief engineer's department, was permitted to take out full patent rights for his invention in connection with the construction of electric junction boxes and similar chambers for the prevention of gas and water accumulations.

Electrically-driven Escape Vans for Fire Brigade.—As reported in last week's ELECTRICIAN, the Fire Brigade committee brought up a recommendation for the purchase of three electrically-driven motor (escape) vans from the Cedes Electric Traction Co. for £2,957. 10s. 1d.

The chairman of the committee (Hon. H. Lygon), in submitting the recommendation, assured the Council that the Fire Brigade committee had taken the advice of experts in the matter. In order to soothe the heartburnings of those who objected to the contracts being given to a foreign firm, he could say that a great portion of the work would be done in England. The Cedes Electric Traction (Ltd.) is to be allowed to sublet to the Austrian Daimler Motor Co. the supply of chassis fitted with wheel motors, and to the Tudor Accumulator Co. the supply of the batteries.—The recommendation was adopted.

L.C.C. Tramways.—On Tuesday the Highways committee recommended County Council to apply for Parliamentary powers to construct a number of additional tramways (about 22 miles of single line) at an estimated cost of £462,470. The proposed lines are:—

(i.) Marble-arch to Cricklewood, via Edgware-road, Maida-vale, High road Kilburn and Shoot-up-hill. (ii.) Chalk Farm-road to Child's-hill, via Chalk Farm-road, Adelaide-road, Upper Avenue-road and Finchley-road. (iii.) Kilburn High-road to Upper Avenue-road, via Kilburn-priory, Alexandra-road, Hillgrove-road and Adelaide road. (iv.) Marylebone-road to Swiss Cottage, via Upper Baker-street, Park-road, Wellington-road and Finchley-road. (v.) Edgware-road to Upper Baker-street via Marylebone-road. (vi.) King's-road to junction of Fulham-road and Elm Park-gardens, via Beaufort-street and Fulham-road. (vii.) Fulham-road (Elm Park-gardens) to Brompton-road, via Fulham-road. (viii.) Diversion of South Lambeth-road tramways, via Archer-street and Bond-street. (ix.) Additional tracks on Dog Kennel-hill. (x.) Further extension westward of tramways in Tooley-street from Duke-street.

The conduit system will be used on all these routes except (iii.), on which the trolley system will be employed, and either the conduit or trolley will be adopted on the first route. Consideration of the report has been deferred for a week.

Light Railways.—The Light Railway Commissioners have decided to grant an order to Birmingham Corporation to construct and work railway No. 5, and by agreement with the Hales Owen Light Railway Co. to purchase so much of railway No. 1 (running through Hales Owen and Quinton to Balden-road) as lies jointly in the city and the Urban District of Oldbury, provided the Council will pass a special resolution applying for the Order, and will by resolution undertake to complete railway No. 5, so that it shall be ready for inspection by the Board of Trade at the same time as the other Hales Owen railways are inspected. Birmingham Tramways committee recommend their Council to pass these resolutions.

The Weston-super-Mare Light Railway Order (authorising the construction of a light railway connecting the Weston, Clevedon & Portishead Light Railway and the tramways of the Weston-super-Mare & District Electric Supply Co.) has been submitted to the Board of Trade for confirmation. Objections by Aug. 10.

Digitized by Google

On Tuesday the Light Railway Commissioners held an inquiry into the application for an order to construct a funicular railway on the Malvern Hills, up the Rushy Valley to within 90 ft. of the top of the Worcestershire Beacon.

After hearing the evidence the Commissioners said that as the railway would be over common land the consent of the Board of Agriculture would be necessary, but, subject to that, they were prepared to grant an order for the construction of the line, as they felt that the balance of public opinion was in favour of it.

Llanelly.—A Board of Trade inquiry was held here last week into the objections made by owners of houses within 200 yards oft he site of the proposed generating station of the Llanelly & District Electric Light & Traction Co. As a result of the inquiry all objections were removed, and the contractor (Mr. G. Mercer) proceeded with the work.

Municipal Telephony.—At the meeting of the Hull Telephone committee on Tuesday it was reported that Mr. Bentham had put a question in the House of Commons to the Postmaster-General as to the future of municipal telephony, and in reply the Postmaster had stated that the taking over of the National Telephone Co.'s undertaking had been definitely settled. As to the question of the Hull municipality, that was quite another matter. In all probability they would be left in the position in which they were if it was the general desire.

Municipal Wiring.—On Saturday last Barnstaple Council adopted a recommendation of their Electric Light committee that further expenditure on an electrical exhibition was undesirable until satisfactory arrangements had been made for the proper display and supply of fittings, and further facilities afforded for wiring premises of prospective consumers.

Coun. J. T. WHITE said even opponents of municipal trading seemed to be forced to the conclusion that there was only one alternative, and that was for the Council to acquire wiring powers. They would have to consider some means for increasing the sale of electricity amongst private consumers.

Coun. BARRETT said an application for a provisional order to empower the Council to wire premises would cost about £100, and, having regard to the strong opposition which would no doubt be offered, it was doubtful if the order would be secured.

Newport (Mon.).—At the last meeting of the Council it was decided that £3,500. 5s. 10d., standing to the debit of the electricity capital account in respect of superseded plant, should be paid out of the electricity revenue account or out of the general district fund. It has also been decided to apply for sanction to borrow a similar sum repayable in three years.

Penzance.—Mr. W. T. Pressland, acting for the Penzance & District Electric Supply Co., has informed the Council that his company has made arrangements for a bulk supply of electricity from the Cornwall Electric Supply Co.'s station at Hayle, the necessity for a generating station in Penzance being thereby avoided. A supply of electricity would be available in Penzance by Dec. 31, 1911, and the Council were asked to agree to allow their provisional order to remain in force and to ask the Board to postpone its revocation, so that the works might be carried out. The matter was referred to the Electric Lighting committee.

Presentation.—At the Hylton-road electricity station (Sunderland) on Thursday evening last week Mr. Harry Webber, late works superintendent, was presented with a gold chronometer stop watch by the staff of the Corporation electricity department on his leaving to take up the position of borough electrical engineer at Keighley. The presentation was made by the borough electrical engineer and manager (Mr. Alfred S. Blackman), who, in a few well chosen words, eulogised the good qualities of Mr. Webber, and wished him success in his new sphere of duty. Mr. Windle (assistant engineer), Mr. Crowther and Mr. Donkin also spoke, and Mr. Webber suitably responded.

Preston, Chorley and Horwich Tramways.—There is a prospect of this tramway scheme, which has been before the public for some time, being carried out. The Anglo-Continental Industries (Ltd.) has agreed to finance it, provided some of the required capital is found locally.

Provisional Order Revocation.—The Board of Trade have revoked the Sutton-in-Ashfield Urban District Electric Lighting Order, 1904, as from July 12.

Rhyl.—The Electric Light committee offer to supply electric current to the L. & N.W. Railway for lighting and power at the local station at 5d. per unit up to 10,000 units per annum, and if this figure is exceeded the price will be 4d. per unit.

School Lighting.—Bath Education committee have decided to adopt electric lighting at the Long Acre Technical Institute.

On Wednesday the L.C.C. Education committee decided to instal electric lighting in an extension of a technical institute by direct employment of labour at a cost of £350, and alterations are also to be carried out to the existing installation at a cost of about £130.

London-road schools and the special instruction centre, Southend, are to be wired.

South Africa.—The annual report on the Central South African Railways for 1909 states that the purchases by the administration during the year included electrical material purchased in South Africa £4,006 and in Europe £3,158, machinery £389 and £2,600, waste £309 and £1,213, engine, carriage and waggon parts £222 and £34,889, pipes and fittings £1,654 and £1,752. Steel culvert pipes (all purchased in Europe) £6,492.

Stretford.—An unopposed inquiry was held last week into the application of the Council to borrow, amongst other sums, £2,150 for additional plant for the electricity works.

The Electrical Committee.—This committee met recently, and it was decided that the president, vice-president, hon. treasurer and hon. secretary should form a committee of management entrusted with power to call meetings when necessary and generally prepare the business for the committee. Those interested in the electrical industry are requested to communicate with the hon. secretary, Bank Buildings, Kingsway, London, W.C., with reference to any question that they may wish to bring before the committee. The president has been requested to make endeavours to form a Parliamentary party in the House of Commons, and he will welcome any suggestions as to the composition of that party which may be addressed to the hon. secretary.

Torquay.—At a private meeting of the Council on Wednesday a report prepared by Messrs. Mordey & Dawbarn on the local tramways was presented.

In their report Messrs. Mordey & Dawbarn state that, in their opinion, the present Dolter system could be improved and perfected so as to render it satisfactory, and also that another surface-contact system could be substituted if necessary. An offer has been made to replace the parts of the stud which had given trouble by a simplified and improved modification by Mr. E. A. Mitchell, who was engineer to the company when the system was put down. They were of opinion that the studs so modified would give greatly improved results, and would be more easily obtained. They understood Mr. Mitchell had offered to adopt his modification to the studs on a mile of track free of cost, on the condition that if satisfactory it should be applied to the whole line. The cost would be £590 per mile, or a total of about £6,500, considerably less than the £10,000 they understood the company was prepared to expend in putting up a trolley system and in removing the studs and making good the roadway. They thought the company should be strongly urged to adopt Mr. Mitchell's proposal.

The Tramway committee were authorised by the Council to take such further action as may be necessary or expedient to retain a surface-contact system.

Wealdstone.—The Harrow Electric Light & Power Co. propose to apply for a provisional order for Wealdstone, Harrow Weald, Pinner, and Great Stanmore.

Wireless Telegraphy.—The owners of the White Star Line have made a departure by putting into commission a training ship intended primarily for the training in wireless telegraph work of a number of young men for employment in the White Star and associated companies. The "Mersey," a sailing ship, has been equipped with Marconi apparatus. She sails from Liverpool on July 28 for Australia.

Workhouse Lighting.—The South Dublin Guardians have received sanction from the L.G. Board to borrow £3,000 for electric lighting plant.

Sports.—The annual sports of Croydon Corporation Tramways Athletic Club took place last week in fine weather and in the presence of nearly 6,000 spectators. The funds will show a considerable surplus for the benefit of local hospitals.

FOREIGN.

Germany.—H.M. representative in Baden reports that a supplementary estimate has been laid before the Baden Diet for the preliminary works in connection with the erection of hydro-electric works in the Murg Valley (Black Forest) above Forbach.

The electrical energy generated will be used by the State railway administration for lighting, for motive power at the railway stations, for the workshops, and at the harbour works at Mannheim. It is not proposed at present to utilise the power from this station for traction. The total cost of the works (with cables) is estimated at 26,784,000 marks (about £1,317,000), and the first half of the work is to be taken in hand at once.

Electrical Progress in Japan.—With "The Times" of Tuesday there appeared a special illustrated supplement giving a mass of information relating to the history, the physical characteristics and the scientific, industrial and educational progress of Japan.

It is stated that at the end of 1909 the electric light, power and traction enterprises numbered 879 (of which 111 were not in operation), with a

Digitized by Google

capacity of 439,877 kw. (of which 247,963 kw. was not available), and the capital invested in these undertakings was 166,396,440 yen (£16,674,310), increases, compared with 1905, of 70 per cent. in the number of undertakings, 353 per cent. in plant capacity and 206 per cent. in capital. The first electricity supply undertaking was that of the Tokyo Electric Light Co., which started in 1887 with one generating set of Japanese make, and this was followed by Kobe, Osaka, Kyoto, Nagoya and Yokohama and other towns, and there are now few large cities or towns without electricity supply. Though an electric tramway was constructed in Tokyo in 1890, the earliest used for public traffic was opened in Kyoto in 1895. The first hydro-electric undertaking was commenced in 1891. The tramways in operation include 17 electric and 37 horse. The total capital invested in tramways is 89,037,000 yen (£9,089,194), and the length of the lines is over 550 miles. There are 186 electricity supply undertakings (55 not in operation), with 263,016 kw. of plant, and at December, 1908, there were 318,339 consumers with 1,230,876 lamps, besides 3,688 power consumers with 3,978 motors (17,093 H.P.). Of the total plant mentioned above (439,877 kw.) 254,437 kw. is (or will be) operated by water-power and 185,440 kw. by steam, gas or other power. The motors in use in metalliferous mines in 1908 were 562 (19,842 H.P.) and in non-metalliferous mines 299 (10,461 H.P.). Although the manufacture of electrical machinery in Japan is of recent origin, it has grown rapidly, and almost all kinds of general machines, tools, wires, cables, lamps and other materials can now be obtained from works in the country, and insulators can now be manufactured for currents of the highest voltage. There are more than 50 establishments engaged in the electro-chemical industries. The first telegraph line for public use was between Tokyo and Yokohama, and was constructed by Mr. W. H. Stone, an Englishman, who is still in the Government Telegraph Department. There are now 3,933 public telegraph offices. The domestic telegrams transmitted in 1909 were some 25,140,000, the telegraph revenue in 1908 was 8,153,900 yen (£832,377), and the expenditure 5,830,400 yen (£595,187) At the end of 1909 there were 424 telephone exchanges and 932 telephone offices, and 95,271 subscribers connected, besides applicants amounting to nearly half that number awaiting connection. Telephone revenue and expenditure in 1908 were 5,262,000 yen (£537,163) and 1,835,000 yen (£187,323) respectively. Japan is an adherent to the International Wireless Convention. The system used during the late war was the work of two Japanese inventors. The use of wireless telegraphy was until quite recently confined to the army and navy, but messages from foreign steamers are now received at the coast stations for transmission to the Japanese telegraph system. The steep gradients of the railways and the presence of a large number of tunnels suggest the advisability of using electric power on the railways, and the available water-power is abundant. A special committee was appointed in 1909 to consider this subject.

Russia.—Vice-Consul D. Young reports that a Belgian company, which constructed and controls the electric lighting and tramway undertakings in Sevastopol, has obtained a concession for the construction of an electric tramway, &c., at Simpheropol, the chief town of the Crimea.

ELECTRICITY SUPPLY AND TRAMWAY ACCOUNTS.

Hastings.—The total income of the electricity department for the year ended March 31 was £17,627 (11·08 per cent. on capital expended), against £16,848 (10·78 per cent.) in 1909.

Receipts from the sale of current by meter were £13,125 and from public lighting £3,750, meter rental, &c., making up the balance. Expenditure was £9,704, leaving a gross profit of £7,923 (against £7,334) to meet interest (£5,168), sinking fund (£5,621), &c. The net deficit was £2,919 (against £3,801), which the borough electrical engineer (Mr. R. F. Ferguson) states is due in a great measure to the fact that people will not wire their houses for the supply and no new buildings are being erected. Mr. Ferguson also considers that the excision of the clause from the Electric Lighting Act, 1909, conferring wiring powers, &c., on local authorities handicaps the department (which is working under a provisional order), as he has received numbers of applications for houses to be wired under some such system. Metal filament lamps have also caused a drop in the number of units sold. 846,546 units were generated (against 870,323); 569,848 were sold to private consumers (against 616,269) and 162,066 were supplied to the public lamps (against 139,103). There are 1,067 consumers (against 1,001); there are 115 lamps for public lighting (against 113) and the total maximum supply demanded was 530 kw. (against 591 kw.).

Ilford.—At the meeting of the Council last week the chairman of the Tramways committee (Mr. R. Stroud, J.P.) presented the report and accounts of the tramways department for the year ended March.

The total income was £27,580, and included £25,709 from traffic receipts. Total expenditure was £18,523 and gross profit £9,058. Interest required £4,364 and instalments of principal repaid £4,211, and after crediting the account with £557 (received from the electricity department for instalment and interest on machinery used wholly for the generation of electricity by the electricity department) there was a net balance of £1,040, which has been placed to reserve and depreciation. Capital expenditure is £148,274 and loan repayments £25,591. 7,274,398 passengers were carried and 666,344 car-miles run. 976,513 units of current were consumed (1·36 per car-mile) and the percentage of working expenses to receipts was 67·2.

Marylebone (London).—The accounts of the electricity department for the year ended March 31 were presented to and approved by the Council at their last meeting.

Receipts from the sale of current by meter were £152,868, from public lighting £4,998, and meter rental £5,859, the total income being £164,092. The cost of generation was £22,367, distribution £6,273, rents, rates and taxes £4,628, management expenses £7,760, and with legal and special expenses the total expenses were £42,052, leaving a gross profit of £122,040. After paying interest and sinking fund charges, &c. (£113,733) there was a balance of £8,482 on the year's working. After meeting sundry expenses incidental to change of pressure and other small items, the net balance (£6,369) was carried forward. 13,910,922 units were generated, 10,033,457 units were sold to private consumers by meter (against 8,843,089 in 1909) and 743,002 (against 157,772) to the public lamps (87 arcs and 2,179 incandescents). The total maximum supply demanded was 7,824 kw.

The report of the electric supply committee states that the total capital expended is £2,037,276, an increase of £12,874 during the year; but the net liability on loans account is £1,955,590. The committee do not anticipate the necessity, apart from special circumstances, for raising further capital other than relatively small amounts (about £5,000 a year) for service lines, meters, &c., for new consumers, and short extensions of the network. The increase in the number of units sold was unprecedented, and was due chiefly to important additions to the consumers' roll. Generation expenses were £43,273, against £44,606 in previous year, a decrease of £1,333, although the output increased by 19·7 per cent. Costs per unit sold were 0·961d. (against 1·19d.) The work of installing electric lamps for public lighting made rapid progress during the year, and 2,179 lamps had been dealt with at March 31, the saving to the rates amounting to £1,630 per annum. Work has been commenced on the remaining 1,100 lamps.

In moving the adoption of the report and accounts, Ald. Debenham gave particulars of the bonus scheme (referred to in our last issue), and said this scheme had already been in operation at the generating station, and had been found very satisfactory. As the result they had economised to the extent of £15,000. He considered that the electricity report was extremely satisfactory under all the circumstances, especially considering the short time the Council had had control of the undertaking. The cost of generating and distribution had decreased, and would continue to decrease. They had steadily reduced the prices charged, and they hoped to still further reduce them.

South Shields.—The borough electrical engineer (Mr. J. H. Cawthra) has issued his report (with accounts, diagrams, &c.) for the year ended March 31.

Capital expended is £184,627, an increase of £2,363 on the year. Total revenue was £25,071 (against £25,559), including £14,590 from private consumers (1,448,803 units at average of 2·42d. per unit, against £14,188, or 1,245,722 units at average of 2·73d. in 1908-9), £3,656 from public lighting (548,217 units at 1·26d., against £3,649, or 547,704 units at 1·28d.); £6,261 from tramways department (1,078,981 units at 1·39d., against £7,107, or 1,235,082 units at 1·38d.); and £564 from the Jarrow Tramways Co. (90,295 units at 1·5d., against £616, or 98,531 units at 1·5d.). Working expenses were £13,430, leaving a gross profit of £11,641 to meet interest on loans (£5,246) and sinking fund (£6,501), leaving a deficit of £106, which, together with the loss of £103 on Holborn Quay, makes a total deficit of £209 on the year's working (against a profit of £1,209 in 1909). The works costs were 0·63d. (against 0·62d.) and the total costs (including interest and sinking fund) 1·85d. (against 1·81d.). The equivalent of 133,703 35-watt lamps is connected (against 99,481), and the total horse-power of motors is 2,540, against 1,184. There are 1,474 private consumers (against 1,366), and for public lighting there are 94 arcs and 484 incandescents (as in 1909). The maximum supply demanded was 1,760 kw. (against 1,653 kw.) and the load-factor 20·53 per cent. (against 21·59 per cent.).

Mr. Cawthra attributes the deficit to the effect of metal filament lamps upon the revenue, and points out that in 1908 (when there were only 1,313 private consumers) the lighting output was 4,515,495 and last year (with 1,474 consumers) the output dropped to 1,380,881 units; the revenue from private lighting in 1908 was £14,300, against £12,412 last year. The revenue per 35-watt lamp equivalent was 2s. 8d. last year, against 3s. 7d. in 1908-9.

Accompanying the report is an interesting table, showing the number and classification of power consumers.

Stepney (London).—The total capital expended on the electricity undertaking at March 31 last was £356,259, an increase of £36,281 on the year.

Income from sale of current for private lighting, power and heating was £42,454 (against £37,852) and from public lighting £6,199 (against £6,013). After allowing for irrecoverables and adding miscellaneous receipts, &c., the total income was £52,266, against £46,934. Expenses of generation (including £12,290 for fuel, steam and electricity purchased in bulk) were £21,298, and total expenditure was £31,450 (against £28,748), leaving gross profit £20,816 (against £18,186). After paying interest (£10,850) and providing for repayment of debt (£7,955) and other items there was a net balance of £1,515 (against £1,808). The units sold for private lighting were 3,027,894 (increase 191,826), for power and heat 3,388,215 (increase 829,630), for public lighting 1,165,372, and bulk supply 427,693 (increase 118,253) a total of 8,009,174 (increase 1,175,309). The total lamps connected during the year were equal to 74,134 30-watt lamps (against 65,550); there are 484 arcs and 122 incan-

Digitized by Google

descents for public lighting (as in 1909), and the maximum supply demanded was 3,669 kw. (against 3,248 kw.). The works cost per unit sold was 0·669d. (against 0·692d.), the total cost (including interest and sinking fund) was 1·445d. (against 1·505d.), and the average income for the total supply was 1·458d. per unit (against 1·540d.).

In the report of the engineer and manager (Mr. W. C. P. Tapper) it is stated that the outstanding feature of the year's operations was the opening of the Council's Limehouse station (on Oct. 27, 1909) by the Hon. Harry and Mrs. Lawson. The station was started and actually supplying current within 13 months from the commencement of the work on the site. An unusual feature in connection with the starting of the station, and one which added greatly to the difficulty of the work, was that it involved the removal from the Whitechapel station of boilers and turbo-generators to the extent of 2,000 kw., half of which was transferred during 1909, and the remainder is now in course of removal. In order to enable the transfer to be effected without endangering the supply, energy had, during the year, been purchased in bulk from Poplar Council to the extent of 1,027,429 units. This bulk supply is interesting as being the first case of "linking-up" under the London Electric Supply Act, 1908. Whilst the net profit is no measure of the success of an undertaking conducted primarily for the benefit of the ratepayers of the borough, it is satisfactory to be able to show, after meeting all expenses and loan charges out of revenue, a surplus of £1,515, notwithstanding that the average income per unit is only 1·458d. —the lowest in London. In his report for the year 1907-08, Mr. Tapper pointed out that, owing to the charges on unproductive capital at Limehouse station, a call upon the reserve fund might be anticipated for the first year or two after that station started working. As, however, the percentage yield of gross profit has proved to be as high as 6·16 on the capital expended—the additions during the year being averaged, it has not been necessary to call upon reserve to meet any of the increased capital charges. A large proportion of the expenditure (viz.: £1,073. 14s. 5d.) on removal of plant and machinery from Whitechapel to Limehouse was incurred during the past year, and a sum has to be written off capital expenditure, in respect of various plant and material rendered useless by the removal. This to date of accounts amounted to £1,262. 11s. 5d., and these items have been charged to reserve. The whole balance of the somewhat heavy preliminary expenses incurred at Limehouse has also been charged to reserve, in order to wipe the item out of the capital account. The value of the plant transferred to Limehouse during the year was £10,240. 0s. 3d. Most satisfactory increases would be noted in the maximum load, units generated and sold, and in lamps connected. The increase in units sold for power and heating was in advance of last year's record, whilst the private lighting units were still being influenced by the adoption of the metal filament lamps. Although the increase in total units sold was greater than in any previous year, the increase in units supplied to feeders was less than that of the previous year. That was due to the reduction effected in distribution losses by the running of the Limehouse station. The total additional lamps connected during the year was greater than that for any previous year, and there again the progress in power connections was very satisfactory. The private lighting connections show signs of recovering from the set-back received from the introduction of metal filament lamps, and the large increase in bulk supply connections was accounted for by the decision of the Port of London authority to take, during the summer months, current from the Council for the whole of their property in Stepney. The total connections (in 30-watt lamp equivalents) at March 31 last was 385,265, viz., private lighting 129,659, power and heat 226,325, public lighting 9,558, and bulk supply 19,723. Of the total of 149,382 lamps connected for private lighting and bulk supply, no less than 30,000 are connected on the "restricted supply" system. In other words, a total of 900 kw. is connected and excluded from the maximum load, and for which no provision has to be made in capital expenditure, apart from service costs and meters. With reference to the average costs per unit sold, a considerable reduction may be anticipated for the current year, when the necessary arrangements will be completed for obtaining coal in barge "alongside" at the Limehouse station, and the condensing plant put into commission. The cost of repairs and maintenance keeps at a reasonably low figure, partly due to economy effected by the annual overhaul of the machines being carried out by the Council's own staff, and partly due, also, to the remarkable freedom from serious faults on the distributing mains.

Salford.—The report of the general manager of the municipal tramways (Mr. G. W. Holford) for the year ended March states that the gross capital expenditure is £719,348.

Traffic revenue was £237,502 and total receipts £242,960. Working expenses were £152,002, and after paying interest (£24,101), sinking fund (£21,726) and rent to outside authorities (£25,958) there was a net balance of £19,172, of which £17,000 was voted to relief of rates and £2,172 carried to depreciation and renewals. 5,647,428 car-miles were run and 45,940,775 passengers carried; 9,094,699 units of current were used, or 1·63 per car-mile. The percentage of working expenses to receipts was 64, the average total revenue per car-mile was 10·33d. and the average fare per passenger 1·24d.

West Ham.—The gross receipts of the tramways for the year ended March were £127,066, against £115,813 for 1908-9. The net profit is £7,000, compared with £5,923.

Since the linking up of part of the system with that of the London County Council at Bow Bridge, the average receipts in West Ham have been about £250 a week more than those for the corresponding weeks of last year.

TRADE NOTES AND NOTICES.

TENDERS INVITED.

London County Council invite tenders for the wiring and fitting for electric lighting of the second section of the central car repair depot, Woolwich-road. Specifications, &c., from the Clerk of the Council, County Hall, Spring-gardens, S.W. Tenders by 11 a.m. Tuesday, Aug. 30. See also an advertisement.

Tenders are invited up to Sept. 7 for supply of battery material and glassware to the Postmaster-General's Department in Queensland. Tender forms and specifications from the Official Secretary in Great Britain of the Commonwealth of Australia, 72, Victoria-street, London, S.W. See also an advertisement.

Dublin Corporation invite tenders for 12 months' supply of machinery oils for their electricity works. Specifications, &c., from the town clerk, Mr. Henry Campbell, City Hall, Dublin, where tenders (addressed to the Chairman of the Supplies committee) must be in by Friday, 29th inst. See also an advertisement.

Newport (Mon.) Electricity and Tramways committee invite tenders for supply of carbon filament electric lamps, radiator lamps (British made), flame arc lamp carbons for Excello and Oliver type lamps, and a.-c. and d.-c. two-rate and prepayment meters, during the ensuing 12 months. Specification and schedule from the borough electrical engineer and tramway manager, Mr. H. Collings Bishop, M.I.E.E. Tenders to the Town Clerk, Town Hall, Newport, Mon., by first post Aug. 15. See also an advertisement.

Belfast Harbour Commissioners invite tenders for supply and delivery into the Alexandra Graving Dock engine house, Belfast, of of 3¼ miles of 7/18 paper insulated lead-covered h.t. cable, served with jute, and suitable for 3,000 volt continuous current: also ½ mile 7/18 rubber insulated cable to sample. Specification, forms of tender, &c., from the harbour engineer, Mr. W. Redfern Kelly, M.Inst.C.E. Tenders to the secretary, Mr. W. A. Currie, Harbour Office, Belfast, by 27th inst.

Belfast Harbour Commissioners also invite tenders for the construction, delivery and erection at their electric light station of an independent surface condensing plant, with oil separator, &c. Specification and form of tender, &c., from the harbour engineer, Mr. W. Redfern Kelly, M.I.C.E., and tenders addressed to the secretary, Mr. W. A. Currie, Harbour Office, Belfast, by July 27.

London County Council want tenders by 11 a.m. July 26, for supply of 4,800 steel tyres for driving wheels, and 1,600 steel tyres for pony wheels for tramcars. Forms of tender, &c., from the Chief Officer.

The Secretary of State for India requires tenders by 2 p.m. Aug. 3 for supply of overhead floating staging and electrically-driven water supply pumps. Conditions, &c., from the Director-General of Stores, India Office.

Chorlton Guardians want tenders by July 26 for the re-plating, &c., of an accumulator at the Cottage Homes, Styal, Cheshire. Specifications, &c., from Mr. F. W. Page, 14, St. Ann's-square, Manchester.

Morecambe Corporation want tenders by July 28 for feeder pillars and arc lamp carbons. Specifications, &c., from the Borough Electrical Engineer.

Chelmsford Education committee want tenders by Aug. 31 for electric light wiring at Trinity-road school. Forms, &c., from Mr. W. H. Pertwee, London-road, Chelmsford.

Manchester Electricity committee want tenders by noon Aug. 2 for supply and erection of induced draught plant at Bloom-street generating station. Specifications, &c., from Mr. F. E. Hughes, Town Hall, Manchester.

The Deputy Postmaster-General, Brisbane, will receive tenders until noon Sept. 7 for supply of glass cells, corks and tubes and porous cups for batteries, battery material, chemicals, &c. Specifications, &c., from the High Commissioner for the Australian Commonwealth, London. Local representation is necessary.

The Deputy Postmaster-General, Melbourne (Victoria), will receive tenders until 3 p.m. Aug. 30 for supply of electrical sundries, insulators, wire and sulphate of magnesia. Local representation necessary. Further particulars from 72, Victoria-street, London, S.W.

The Transvaal Administration of Posts and Telegraphs require tenders for supply of 2 miles of 64-conductor switchboard cable. Further information from 72, Victoria-street, London, S.W. Tenders to Pretoria by July 27.

Invercargill (N.Z.) Borough Council require tenders for construction of 8 miles of electric tramway, including overhead equipment, supply of power house plant, &c., and eight motor cars. Tender forms, &c. (on deposit of £1) from the Town Clerk.

Digitized by Google

The Italian State Railways Administration, 16, Via Ludovici, ROME, want tenders by Aug. 22 for supply of 584.000 common carbons for arc lamps. Only firms on list kept by administration are generally allowed to tender. Local representation is practically necessary.

The Turkish Ministry of Commerce and Public Works want tenders by Oct. 28 (Nov. 10) for a concession for the construction and working of electric tramways in CONSTANTINOPLE and suburbs. A deposit of £13,500 (sterling) is required with each tender. Local representation is essential. Copy of specification (in French) may be seen at 73, Basinghall-street, London, E.C.

The Maire of BOURGES (Cher, France) will receive tenders until Aug. 4 for supply of 24 three-phase asynchronous motors.

Tenders will be received at the District Offices, TOLNA (Hungary), on Aug. 16 for erection and equipment of an electric power station.

The French Government Telegraph Department, PARIS, will receive tenders until July 28 for supply of 505 tons of various sizes of g.i. wire, and until July 30 for supply of bronze and copper wire and 2,090,000 porcelain or glass insulators.

TENDERS RECEIVED AND ACCEPTED.

London County Council have accepted the following tenders :—

Brush Electrical Engineering Co. (lowest tender) for supply of 250 bogie truck double-deck roof-covered car bodies, £94,375. (Six tenders received, highest £143,750.)

Heenan & Froude (lowest) for 250 swing bolster trucks, £28,750. (Five tenders ; highest £34,000.)

British Westinghouse Co. (lowest), 250 electrical equipments, £83,812. 10s. (Three tenders ; highest £86,187. 10s.)

British Westinghouse Co., 250 sets of magnetic brake equipments, £14,250 (same price as existing contracts).

Dick, Kerr & Co. (lowest), alteration of superstructure of Battersea Bridge, £6,843. 17s. (Thirteen tenders ; highest £11,759. 7s. 5d. Chief engineer's estimate, £6,995.)

Western Electric Co. (lowest), low-tension cables, cable boxes, &c., for central car repair depot, £948. 14s. 2d. (Seven tenders ; highest £1,053. 4s. 6d. Chief officer's estimate £980.)

Maritime & General Improvement Co., insulating varnishes for electrical purposes, £105.

The L.C.C. Education committee have accepted the tender of the Central Motor Engineering Co. (at £175. 12s. 6d.) for wiring St. Mark's-road School, Kensington, and also for wiring the Haverstock Hill (St. Pancras) School at £240. 14s. 6d.

The Metropolitan Asylums Board has placed the following orders :

Speedy, Eynon & Co., extensions to internal telephones at N.E. Hospital, £29 ; United Electric Car Co., alteration to fittings of ambulance tramcar for small-pox hospitals, £22. 15s.

West Ham Education committee received 25 tenders for wiring three schools. The contract for the Clarkson-street school was let to Newbald & Co. (who will use the Stannos system) at £153. 10s., and Weston & Sons secured the order for the other two schools (which will be wired on the Simplex system) at £136. 11s. and £115. 13s. respectively. In each case the lowest tender was accepted.

Barnes Council have placed an order with Siemens Bros. & Co. to lay and joint the Boileau Arms and Clifford-avenue feeders at 4½d. per yard.

Twickenham Council have accepted the tender of Stuart & Moore for supply of three additional fire alarm posts and connecting same to existing indicators on the fire alarm switchboard for £74. 15s.

Lowestoft Council have accepted the tender of the Standard Cable Co. (at £326) for supply of cable.

Darlington Council have placed an order with the Gilbert Arc Lamp Co. for 56 arc lamps at £5. 16s. each.

Newport (Mon.) Corporation have accepted the following tenders :

General Electric Co., l.t., h.t. and e.h.t. switchboards for Llanarth-street and Corporation-road generating station, £3,063 ; Balcke & Co., cooling tower, £681 ; and Babcock & Wilcox, superheaters for six boilers, £915 ; Albion Clay Co., four-way ducts for electric cables 3s. 11½d. (less 2½ per cent.) per yard. There were 14 tenders for the switchboard contract, and the lowest tender was accepted.

Carlisle Council have accepted the tender of Pratchitt Bros. for pipework at the electricity works.

Sunderland Electricity and Lighting committee have accepted the following tenders :—

W. T. Henley's Telegraph Works Co., v.i.r. cable for stock and lead-covered cable ; British Insulated & Helsby Cables, service boxes ; J. Thompson & Co., wood troughing ; W. G. Farrow, pavement boxes for stock ; Electric & General Stores, well glasses, lanterns, wall brackets and post brackets ; Crompton & Co., Oliver Arc Lamp (Ltd.) and General Electric Co., carbons ; Sunderland Forge & Eng. Co., bearings and shaftings for converting steam-driven dynamo at Hylton-road works into motor-generators.

Worsley Council have accepted the tender of Allman & Co. for wiring the Town Hall.

Storage Batteries Contracts.—With the present low prices ruling, owing to the depreciated market values of lead, the public are doing exceedingly well in placing their orders for storage batteries. The D.P. Battery Co., of Bakewell, seem to be sharing in the contracts obtainable, and amongst numerous orders they are installing a second large battery at Letchworth for the First Garden City (Ltd.), and they have recently supplied three light and power batteries to the Midland Railway Co., the Melbourne Electric Light & Power Co. and Blackpool Co-operative Society.

The firm are also shipping five batteries to India, China, New Zealand and the Argentine, and they have even been able to ship to the United States, in spite of the tariff.

In reference to the recent meeting of mining engineers in London, where a statement was made that storage batteries entailed the attention of a highly skilled engineer, whilst such services are admittedly desirable in the case of a large central station installation, it is estimated that in fully 95 per cent. of small installations batteries are in use without skilled attention with excellent results.

BUSINESS NOTICES.

Owing to the greatly increased volume of their speedometer and motor accessory business, Messrs. S. Smith & Son have established a telephone exchange at 9, Strand, London, W.C., so that their customers may be switched through to the correct department without delay. The firm's new numbers are Gerrard 9,201 (3 lines).

Messrs. Hogan & Wardrop have removed from Gloucester Mansions, Charing Cross-road, to 2, Gresham-buildings, Basinghall-street, E.C., London.

The increased facilities will enable the firm to carry larger stocks of their fans and small motors, as well as a full range of the various switchgear manufactured by the Midland Electric Manufacturing Co. Cryselco incandescent electric lamps and the manufactures of the Electrical Conduit & Fittings Co., of Walsall, will also be stocked. The new telephone number of the firm is London Wall 723.

Mr. Walter H. Derriman, B.Sc., A.C.G.I., A.I.E.E., fellow of the Chartered Institute of Patent Agents, has entered into partnership with Messrs. Dicker & Pollak, chartered patent agents, 37, Furnival-street, Holborn, E.C., and the style of the firm has been changed to Dicker, Pollak & Derriman. Mr. Derriman is taking charge of the firm's electrical business.

We are informed that Messrs. James Gordon & Co., 81, Knightrider-street, London, E.C., makers of sectional superheaters, are placing on the market a new patented sectional superheater, which, it is claimed, has many advantages over existing designs.

Plant for Sale.—Two gas driven alternator sets of 250 kw. each are advertised for sale.

Patent Development.—The owners of British Patent No. 23,778 (1907), for "Improvements in the manufacture of electric resistances," desire to sell their patent rights or to grant licences. Applications to Messrs. Day, Davies & Hunt, 321, High Holborn, London, W.C.

The owners of Heys' patents (communicated by Scott, Varley & Anderson), Nos. 1,863/1900, 1,864/1900, and 5,257/1900, relating to "Coils for electrical purposes," desire to grant a licence or to enter into arrangements for manufacturing the patented articles in the United Kingdom. Applications to Messrs. W. E. Heys & Son, 51, Deansgate-arcade, Manchester.

The proprietor of patent No. 18,408/1906, for "Improvements in electric insulators for h.-t. conductors," desires to enter into arrangements for exploiting same in this country. Communications to Messrs. Haseltine, Lake & Co., 7 and 8, Southampton-buildings, London, W.C.

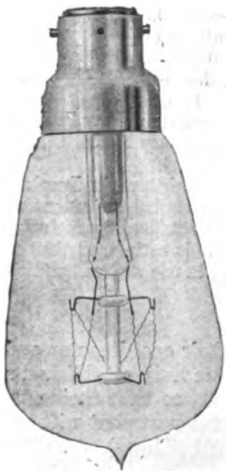
The "Journal."—Part 202 of the "Journal" of the Institution of Electrical Engineers is now ready, price 5s. Particulars of contents are given in an advertisement.

Another Osram Innovation.—In several previous issues we have furnished particulars in regard to the extraordinary length of time that certain Osram lamps have been in use for street lighting in various parts of the country, and in this connection it is interesting to record that occasionally the metal caps have been found to become actually eaten away through prolonged exposure to the elements before the filaments had failed. We learn from the manufacturers that on this account they have decided in future to supply high candle-power Osram lamps with practically indestructible plated copper caps instead of brass as heretofore.

Electricity Supply in Marylebone.—We have received from the general manager of the Marylebone electric supply department two pamphlets dealing with the conduct of electricity supply in his area. The first gives a concise, clear account of the two methods of charging employed—the "maximum demand" and the "telephone" systems—either of which may be adopted at the option of the consumer. The tariffs in force for lighting, heat and power are given, accom-

Digitized by Google

panied by numerical examples which should make the whole matter clear to the non-electrical person. The second pamphlet contains a number of illustrations showing various electric power applications, and should prove of great use to the borough canvassers.



Siemens' "Onewatt" Lamps.—We are informed by Messrs. Siemens Bros. Dynamo Works that they are now placing on the market a range of "One-watt" lamps, suitable for use on 20, 24, 25 and 30 volts and of either 10 or 16 candle-power. These lamps are being supplied with bell-shaped bulb at 2s. and with spherical bulb at 2s. 3d. They should be specially suitable for houses where transformers are used or for train lighting. The accompanying photograph shows one of these lamps, the scale being one-half.

Holiday Arrangements.—For the coming August Bank Holiday the Great Central Railway Co. announce that they have prepared a special programme of excursion arrangements to all parts of their system, and that copies of this programme can be obtained at Marylebone station, at any of the G.C.R. Agencies, or free by post from the Publicity Department, 216, Marylebone-road, London, N.W.

CATALOGUES, &c.

ELECTRO-MEDICAL INSTRUMENTS.—We have received from Messrs. Siemens Bros. & Co. three pamphlets dealing with their large range of electro-medical apparatus. The first of these has been specially produced for the forthcoming British Medical Association Annual Exhibition, which is to take place next week in London, and contains illustrated particulars of many pieces of apparatus. The second pamphlet deals with X-ray tubes and their accessories, and the third with radium salts and radio-active earths. Much useful information to medical men is contained in each of these booklets.

FORTITER THREE-PHASE MOTOR STARTERS.—The Union Electric Co. have issued a catalogue dealing with their well-known make of three-phase motor starters. A perusal of this shows that in it are described some new designs of starter, notably a star mesh switch designed for starting motors with short-circuited rotors. These are fitted with a quick make-and-break device, as well as with a ratchet which prevents them from being operated in the wrong direction.

DUDDELL OSCILLOGRAPH.—We have received from the Cambridge Scientific Instrument Co. a copy of a pamphlet describing recent improvements that have been made in their well-known Duddell oscillograph. A full description, both theoretical and practical, is given, and attention is also paid to the auxiliary apparatus which must be used with this instrument. Some interesting records that have been obtained with this instrument are also given. We understand from the company that they have just received two orders for complete Duddell oscillograph outfits for use on 50,000-volt circuits. One of these orders is from a firm in Tokyo, and the other from a large firm of cable manufacturers in Australia. The company are good enough to point out that probably these orders are the result of the notes we published on this instrument some time ago. We only hope this is the case.

"EXCELLO" LAMPS.—In a list recently issued by the Union Electric Co. an endeavour has been made to summarise in convenient form all the available information relating to the excellent "Excello" arc lamp. These lamps are being made in the same designs and types as hitherto, but attention may be drawn to two patterns which are fitted with a device for automatically cutting out the lamp should it, from any cause, fail to continue burning. Some new types of reflectors and covers are also illustrated. The same company send us a pamphlet giving details of a special lamp designed for cinematograph work.

ALIOTH MACHINES AND TRANSFORMERS.—Mr. J. Stottner forwards his latest price list of electrical material. This is a well-illustrated pamphlet containing details of the machines made by the Alioth Co. of Basle.

BANKRUPTCIES, LIQUIDATIONS, &c.

Ernest Albt. Thorn, electrical engineer, &c., 22, Mossbury-road, Clapham Junction, London, S.W., has been adjudicated bankrupt.

Neville Kaye & Co., Ltd. (electrical and general engineers), is being wound up voluntarily.

The trustee (Mr. E. F. Gardner, 144, Commercial-street, Newport, Mon.) in the bankruptcy of Geo. Sutcliffe (trading as Geo. Sutcliffe & Co.), electrical engineer, 22, George-street, Abertillery, Mon., has been released.

The trustee (Mr. C. J. Band, 8, High-street, Coventry) in the bankruptcy of Ernest Goodman (trading as E. Goodman & Co.), electrical engineer, 30, Hertford-street, Coventry, has been released.

A first and final dividend of 1s. 9¾d. is payable July 25 at 26, Baldwin-street, Bristol, to creditors of Robt. Edwd. Joy (trading as the Bristol Electrical Co.), 143, Cheltenham-road, Bristol.

A dividend is to be paid to creditors of Harry Graham, electrician, &c., Albion-street, Huddersfield. Claims to Mr. E. Netherwood, Cloth Hall-street, Huddersfield, or to Mr. G. W. Smith, 23, John William-street, Huddersfield, by July 29.

A dividend is to be paid to the creditors of Charlotte Rix (trading as Bridgewater & Wright), electrical engineer, 78, York-road, King's Cross, London, N. Claims to Mr. E. H. Hawkins, 4, Charterhouse-square, London, E.C., by July 29.

COMPANIES' MEETINGS AND REPORTS.

United River Plate Telephone Co. (Ltd.)

The twenty-fourth ordinary general meeting of this company was held on Tuesday, under the presidency of Sir IRVING COURTENAY.

The SECRETARY (Mr. David Smith) having read the notice calling the meeting, and the auditors' report,

The CHAIRMAN said: Gentlemen, the result of the year's working has been exceedingly satisfactory, and the company has made excellent progress during the year under review. Subscribers have increased, revenue has increased, the service, we believe, has improved and is improving. By the end of the year we expect all our principal exchanges in Buenos Aires will have been turned over from magneto to common battery working. The new common battery boards, several of which are now working, have been of the most material assistance to us. These changes, of course, necessitate a great deal of other work before the boards can come into use. For instance, existing overhead installations have to be taken down and new distributors connected to our underground plant; but, as far as possible, all this work has been proceeding contemporaneously, and the present year should see the bulk of it completed. Labour troubles (not our own), the rapid development of the demand for telephone facilities, and the Centenary celebrations (bringing as they have done many thousands of visitors into the capital of Argentina) have made the strain in our case exceptionally severe this year; but great as the strain was (on some days the rush of traffic rose to 127 per cent. above normal) our latest advices indicate that we got through without any serious hitch. We are also engaged in erecting a common battery board with a suitable building in Bahia Blanca, where, as I mentioned last year, we have put part of our plant underground; and as a like provision will require, before very long, to be made in Rosario, we have taken the opportunity, when installing a new sub-exchange in that city, to anticipate the conversion of the main exchange and this sub-exchange will be on the common battery system. Our exchange in Cordoba has also been growing, and will require reorganisation soon, and there also a new building will be necessary when we put in the new board. We have opened new exchanges in Florencio Varela and Monte Grande, two important and growing suburban towns to the south of Buenos Aires, and in Maipu on the Dolores Mar del Plata line. I mentioned last year that we were making arrangements for constructing a line to Mar del Plata, which has been described as the Brighton of Argentina. The authorities were anxious that this line should be ready for last season, and, in spite of many difficulties, our people completed this line of about 250 miles in what I should think is record time for such an undertaking. It was opened early in the season. The result has more than fulfilled our expectations. The Azul line, to which reference was also made in last year's report, has enabled us to tap an important district in the centre of the Province of Buenos Aires, and when we are in a position to carry this line right through to Bahia Blanca, as we hope to do before long, we will have an extension of which any company may be proud. Our private branch exchange business is growing rapidly, and is already a valuable adjunct to our business. During the year we have strengthened several of our older provincial lines, enabling them to withstand the violence of the severe storms which from time to time sweep over parts of the country, besides adding additional junction lines between the more important exchange centres.

It is our policy, wherever possible, to own the land and buildings in which our exchanges are situated. During the year we have purchased the premises at Brandzen and Lujan. We have secured a desirable plot of land in Mar del Plata, and we have purchased sites in General Belgrano and Bella Vista, as well as one for the new sub-exchange in Rosario. Suitable buildings for these exchanges are either in course of erection or will form part of the current year's programme. To provide for these various works, it is proposed to make a fresh issue of 40,000 ordinary shares, to be offered to the ordinary shareholders at par.

With regard to the accounts, there are few items calling for special mention. Share capital has been increased by £150,000 by the issue in September last. Sundry credit balances are a little higher, due to increased volume of business. Subscriptions paid in advance have increased by £2,700; the reserve fund is increased by the £25,000 added last year, and we propose to add a further £30,000 for the present year. The reserve fund, you will doubtless note with keen approval, is growing steadily, and in view of the growth of our business and capital the directors attach great importance to this. On the credit side we have

Digitized by Google

spent £130,530 in capital expenditure. The special replacement account stands at £30,447. 18s. We have considered it wise in the past to write down this account as quickly as possible, and we have this year put aside £30,000 for the purpose, which practically clears the account. Our real estate is up by £16,000, representing new buildings and sites for exchanges, &c. The increase of £13,000 in sundry debtors represents, for the most part, payments made on account of the new boards in transit or in course of erection and not yet taken over by us from the contractors. The securities are nearly of the same amount as last year, and it will be a satisfaction to you to know that the market value of these investments is well over the figure in the balance-sheet. Stock of materials has risen considerably, but in connection with our new developments we have naturally to carry large quantities of materials of many and varied descriptions, as in our case we are a great distance from our suppliers. Bills receivable and cash at bankers are together some £11,000 better than last year. There has been a gratifying increase in receipts in the River Plate, and although the expenses abroad have also gone up, still the general result is an increase in the net profit for the year of £8,124. Our secretray, Mr. David Smith, has just returned from Buenos Aires, where he made himself thoroughly acquainted with the staff and the various departments of the business; a visit which will be of much benefit to the company. The directors recommend a final dividend of 5 per cent. on the ordinary share capital (making 8 per cent. for the year, tax free). I now move the adoption of the report and accounts and the dividend recommended therein.

Mr. GEORGE KEITH seconded the resolution.

Mr. MARTIN HERZHEIM said he had followed with much pleasure the statement made by the chairman. The satisfactory conditions on which the chairman had enlarged were chiefly due to two points: first, to the continued increase in the wealth and population and the industrial activity of the Argentine Republic, and, secondly, to the wisdom, care and scientific skill brought to bear upon the management of the company. The chairman, assisted by his colleagues, and by, he believed, their expert adviser, Sir John Gavey, gave time to the affairs of the company for which they could scarcely be sufficiently grateful to him.

After a short discussion, the motion was carried unanimously.

The re-election of Mr. Frederick Green as a director, and of the retiring auditors, was followed by a resolution increasing the capital of the company to £1,500,000 by the creation of 100,000 new shares of £5 each, which was unanimously approved.

The CHAIRMAN then said: I have a pleasant duty to perform—to move a resolution that a sincere vote of thanks be accorded to the Consultative Committee in the Argentine, as well as to Mr. Parker, the general manager, and his staff, and also to Mr. David Smith, our excellent secretary, and his staff in London.

Sir J. GAVEY seconded the motion, which was carried unanimously, and a cordial vote of thanks to the chairman and directors brought the proceedings to a close.

Telegraph Construction & Maintenance Co. (Ltd.)

A half-yearly general meeting of this company was held on Tuesday, under the presidency of Sir JAMES PENDER, Bart.

The SECRETARY (Mr. C. W. Clarke) read the notice convening the meeting.

The CHAIRMAN then said: Gentlemen, I have much pleasure in announcing that the Earl of Selborne has accepted the chairmanship of this company. I feel sure that you will all agree with me in thinking that we are very fortunate in getting so eminently suitable a chairman; he will certainly add great strength to our board. This important announcement quite justifies our summer meeting for once, otherwise it is usually a matter of embarrassment to your Directors that you should be called together at this time without there being any definite business to be laid before you. You will remember that the half-yearly meetings of this company were inaugurated in 1871 in accordance with a wish expressed by a few of the proprietors, that although no accounts could be rendered, a meeting should be held in order that they might hear a few words from the chairman with respect to the position of the company, and have the opportunity of asking questions. These interim meetings no doubt served a useful purpose in the early seventies, when there was a good deal of speculation in shares, and when they were very sensitive to all kinds of surmises and rumours. It has now, however, become a question which the proprietors may do well to consider whether they really care to continue these midsummer meetings. On the present occasion all I have to tell you is that we are very busy. There are details of our work which I might talk about, but every business man in this room knows that it is best not to talk about work which we have in prospect, or concerning any contract we may be expecting. This only incites our competitors to redouble their efforts. On the other hand, if we have secured a contract, it is best not to talk about it, as materials have to be bought, and it is only too easy to put prices up against ourselves by permitting the markets to know what our requirements are. With regard to the immediate past, the newspapers have informed you that during the last half-year we have laid the second longest cable in the world (3,144 miles), between La Plata and Ascension, the longest cable being the Vancouver–Fanning Island section of the Pacific cable, which we laid in 1902, the length being 3,458 miles; but the cable we have laid this year is heavier in the copper conductor, making it the biggest cable ever laid. Everything went well with this work (cheers), and it was successfully completed before the contract date, and well in time for the opening to take place on the occasion of the centenary of the Argentine Declaration of Independence. I have nothing further to announce, except that the interim dividend of 12s. per share (5 per cent.) will be posted to you to-day.

Mr. CROFT thought the shareholders will have heard the announcement just made with respect to the appointment to the board with great satisfaction. It is a great thing for a company of this kind to have such an eminent person as Lord Selborne at the head of affairs. This does not imply that the chair has not been well filled during what I may call the interregnum. You have carried out the duties of chairman in the most satisfactory manner, with the approval not only of your colleagues but of the company generally. With regard to what you have described as the midsummer meeting, you, as I understand, desire the opinion of the shareholders whether this is really necessary. I suppose it would require a vote of the company to do away with the second meeting; but, speaking for myself, I have always thought it unnecessary to hold this meeting, which, after all, is not a half-yearly, but only an interim meeting.

The CHAIRMAN thanked Mr. Croft very much for his remarks. The directors were specially glad to hear the opinion of the proprietors in reference to the interim meeting. He was obliged to Mr. Croft for his reference to the work done by the board and the staff, for which he was sure they would be grateful. The proceedings then terminated.

General Electric Co. (Ltd.)

At the meeting on Tuesday the CHAIRMAN (Mr. G. Byng), in moving the adoption of the report, said that the directors were glad to be able to report a good increase of profits—£95,000 against £78,000 last year. The board had decided to propose as hitherto a dividend of 5 per cent. on the ordinary shares. They were increasing their reserve fund by £22,000 and had commenced a new policy of carrying forward a substantial sum. These measures would considerably strengthen their financial position. Hitherto they had used their credit for their financial purposes, but in future they intended to invest part of their reserve in convertible securities, which they hoped would enable them to rely upon their own resources for the large sums they were sometimes called upon to employ in the business. The balance carried forward exceeded £8,000, enough to cover the full interest on their debentures. The directors were proud of the success which they had lately achieved in the production of telephone exchange equipments. The English telephone industry had in the past been in an ignominious position. They had been especially well fitted to produce telephones, and in the inception of that industry England was far ahead of any other country. Yet, that important industry had been strangled in its infancy, and for over 20 years the English and Colonial telephone companies had had to buy all their equipments and instruments from foreign makers. He was pleased to say that a change had at last been made by the British Post Office. They had been very far-sighted in insisting on getting English made apparatus in spite of deep-rooted prejudice, due mainly to mistaken notions in regard to the economical aspect of the question. The General Electric Co. especially had to thank the Government for much encouragement. The result had been most satisfactory to both parties. They had now completed the installation of one of the largest and most important telephone exchanges in the kingdom—every particle, every screw, being made at their Salford works—as well as, and he was assured, even better than, the foreign equipment which held the monopoly for 20 years. They had also nearing completion the installation of another Post Office exchange. Further, they had well in hand an exchange equipment for the Australian Commonwealth, and they had supplied similar plant to the Indian Government. Besides those exchange equipments, they had manufactured, and were manufacturingl, arge quantities of telephone apparatus for the British Post Office and the Colonies. Moreover, the apparatus was to designs prepared by the company. The prices at which the Post Office was now buying in England were far below the foreign prices paid formerly. For instance, instruments previously supplied by the foreigner were now produced in this country and sold at rates lower than the old prices by various percentages running up as high as 30 per cent. That would explain why they had devoted the whole of Peel Works to the manufacture of telephone apparatus, and they were carrying it on now as a subsidiary company called the Peel-Conner Telephone Works (Ltd.), under the able management of Mr. M. S. Conner. Their biggest enterprise, the Witton Engineering Works, had turned out very good work, and its excellent staff and workers had again increased the reputation of their products throughout the world. They had erected some big plants, not only at home, but in the Transvaal, Australia, India, the Argentine and the East. It was unfortunate that the prices ruling were still unremunerative. They had to rely less upon competitive prices than upon the excellence of their plant. They were keeping the flag flying over their carbon works, although they had not yet been able to show a profit in face of foreign competition. The advent of the flame lamp had helped them very much, and in the making of flame carbons they had succeeded in beating the quality of almost all their Continental competitors. They had been greatly encouraged by the policy pursued by the Admiralty, who had recognised the importance of a carbon factory in England. Their example was being followed by most Government Departments, but they had much to complain of in the action of many municipalities. They had increased their foreign depots and agencies in order to find outlets for their large factories. The preferential duties in Canada and Australia had been of very material benefit to them, and had helped in the employment of hundreds of workpeople throughout the year. The sale and influence of the Osram lamp had fulfilled the board's expectations. The wonderful efficiency of that great invention had reduced the cost of electric lighting to less than that of gas. Thousands of Osram lamps were in use to-day that had burned over 6,000 hours—a durability truly astonishing. They regretted to say, however, that their patent rights had been greatly infringed, and they had been compelled to take legal proceedings against infringers, both on the master patent as well as upon minor patents, of which there are many.

CHATHAM & DISTRICT LIGHT RAILWAYS CO.—For the half-year ended June 30 the revenue was £21,601. 8s. 1d. and the expenses £12,703. 17s. 4d. Deducting rent of Rochester Corporation lines (£1,871. 16s.) and interest (£1,234), and adding amount forward (£298. 10s. 5d.), the balance is £6,090. 5s. 2d. The directors recommend payment of the 5 per cent. preference dividend (£2,940) and of dividend at the rate of 2 per cent. on the ordinary shares (£1,060), carrying forward £2,090. 5s. 2d. Traffic receipts show an increase of £1,242 over those for the corresponding period of last year, and there has been a saving of £117 in the expenses.

CROMPTON & CO. (LTD.)—The directors' report for the year ended March 31 states that competition for business has been keener than ever before, and orders have been difficult to obtain. With a view to keeping the works employed, a considerable amount of business has been taken at works cost, with the result that output has only fallen off to a comparatively small extent. The gross profit realised on trading has not been sufficient to pay administration and selling expenses, while the completing of a large contract in the East has entailed a heavy charge on the year's accounts. Litigation in connection with an order for pumping plant has involved the company in special legal expenses. The loss for the year, after making the usual full provision for depreciation and charging all repairs against revenue, amounts to £20,493. 2s. 10d., compared with a profit of £10,051. 10s. 4d. for the previous year. After providing for debenture interest and other charges shown in the net revenue account, and after deducting the balance brought forward, there remains a debit balance of £23,368. 18s. 9d. The guarantee of the Auxiliary Electric Co. in connection with the earnings of the Electric Supply Corpn. has now expired, and the final adjustment should shortly be arrived at. The directors have decided to write down the company's holding in the Electric Supply Corpn. to £4 per share, taking the necessary amount from the reserve fund for that purpose. The claim under the policy of insurance held by the Auxiliary Co. has been settled on terms which are considered favourable. During the financial year, expenditure on patents and experimental work has been considerably in excess of the average. This increase is in connection with an invention which is likely to prove of great value to the company. All such expenses have been charged against revenue, but £600, being the purchase price of a patent which it was important that the company should control, has been added to patents account. In view of the continued depression in the electrical manufacturing trade, the directors have taken steps to further reduce expenses, and with that view are arranging to move the headquarters of the sales department to the works, which it is estimated will effect considerable economies. Although there appears to be an improvement in the volume of the trade of the country, the slight increase in the demand for electrical machinery has not affected market prices. At the same time, the directors are of opinion that by the exercise of the most rigid economy a margin of profit can be earned, even on the basis of the present low prices. Since the close of the financial year an improvement is noticeable in the value of orders coming from colonial and foreign sources.

DIRECT UNITED STATES CABLE CO. (LTD.)—The report of the directors for the half-year ended June 30 states that the revenue (after deducting out-payments) amounted to £58,556. 0s. 5d., compared with £56,444. 18s. 1d. for the corresponding half-year of 1909. Working and other expenses for the same period (including income tax) amounted to £25,277. 6s., leaving £33,278. 14s. 5d. as the net profit, and making, with £6,859. 11s. 2d. brought forward, £40,138. 5s. 7d. For the corresponding period of 1909, the working expenses and other payments were £25,035. 17s. 3d. Three quarterly interim dividends of 4s. each per share (amounting to £36,426) have been paid, and a final dividend of 4s. per share is now proposed, together with a bonus of 2s. per share (both tax free), making with the three interim dividends 4½ per cent. for the year, a total distribution of £54,639. After transferring £5,000 to reserve, the balance of £4,783. 5s. 7d. is proposed to be carried forward. The reserve fund has been debited with £3,584, cost of cable maintenance, and after being credited with interest on the investments, profit on sale of securities and amount transferred from revenue, the balance now amounts to £533,024. 5s. 1d.

NATIONAL TELEPHONE CO. (LTD.)—The income accrued in respect of the business of the half-year ended June 30 amounted to £1,677,587. 17s., compared with £1,549,136. 2s. 9d. for the corresponding period of 1909, an increase of £128,451. 14s. 3d. Working expenses were £974,757. 7s. 2d., compared with £890,798. 2s. 5d., an increase of £83,959. 4s. 10d. The net result (after deducting P.O. royalties amounting to £161,529. 16s. 1d.) was a profit balance of £541,300. 13s. 8d., compared with £509,210. 10s. 10d. an increase of £32,090. 2s. 10d. The rentals carried forward for unexpired terms of running contracts amount to £1,482,179. 1s. 8d., compared with £1,366,283. 9s., being an increase of £115,895. 12s. 8d. Out of the available balance of £409,093. 14s. 1d. the board recommend payment for the half-year of a dividend at the rate of 6 per cent. per annum on the first and second preference shares, 5 per cent. per annum on the third preference shares, 6 per cent. per annum on the preferred stock, and 6 per cent. per annum on the deferred stock, less tax in all cases. The board also propose to transfer £175,000 to reserve and to carry forward the balance of £15,343. 14s. 1d. £216,873. 14s. was expended on capital account during the half-year in the erection of 16,236 additional exchange and private stations and in the construction of underground works.

NATIONAL TELEWRITER CO. (LTD.)—The first general meeting was held on Monday when the chairman (Sir Wm. P. Treloar) said the working capital, after payment of the purchase consideration, was £52,000. £12,554 had been expended on construction, instruments, exchange and plant. They encountered difficulties with regard to the delivery by the makers of the standard machine parts—difficulties which had delayed their operations. Contracts were placed in July, delivery to be made in November; but the parts tendered for approval did not pass the tests to which they were submitted, with the result that the period of manufacture was unexpectedly prolonged, and deliveries to enable them to assemble the various parts of their machines did not actually begin until January of this year. A competent staff for the assembling of the machine parts was at once engaged and trained; but the first complete instruments were not at the disposal of their contract department until March 1, 1910. They had now obtained orders for upwards of 100 instruments, and, in addition to orders which were pending, trials were being made with the company's instruments by railway companies, hotels and others. They believed the great usefulness of the Telewriter was bound soon to be made evident. They hoped shortly, with the sanction of the Post Office, to complete arrangements whereby messages could be sent through their exchange direct to the cable companies' offices. They had secured and equipped premises where private Telewriter boxes were installed for the use of members of the Stock Exchange, and other installations were in preparation. Until recently their operations had been practically confined to the Metropolis; but they looked forward with confidence to results to be obtained in the provinces. They had appointed agents in the principal provincial centres, and competent mechanics had been trained in their workshops to take over the maintenance of Telewriter installations. They contemplated the early opening of an exchange in the West-End of London.

PHOSPHOR BRONZE AMALGAMATION.—We understand that the London Phosphor Copper & Bronze Co. have acquired the entire assets and works of the Phosphor Bronze Co. (Ltd.) (in liquidation). The businesses have been amalgamated, and are being continued under the name of the Phosphor Bronze Co. (Ltd.), which has a capital of £100,000 and will take over all existing contracts. Mr. Walter Lester, proprietor of the London Phosphor Copper & Bronze Co. has been appointed managing director and chairman of the newly-formed company.

CITY NOTES.

MEMORANDA (July 21).—Bank rate 3 per cent. (since June 9, 1910). Price of silver, 25¼d. per oz. Consols 81¼—82 for money; 81⅜—82 for account. Consols Pay Day, Aug. 4; Stock and Shares Continuation Days, July 26 and Aug. 10; Ticket Days, July 27 and Aug. 11; Pay Days, July 28 and Aug. 12; Mining Shares Carry Over Day, July 25.

PRICES OF METALS (London).—*Copper*, cash, 53⅜; three months, 54⅛. *Lead*, English, 12¾—13; foreign, 12⅝. *Spelter*, 22⅜—22¾. *Tin*, English, 147—149; foreign cash, 148½; three months, 149⅜. *Iron*, Cleveland, cash, 48/11, three months, 49/7½.

ANGLO-AMERICAN TELEGRAPH CO. (LTD.)—The directors have resolved, after placing £5,000 to credit of the renewal fund, to declare an interim dividend for the quarter ended June 30 of 15s. per cent. on the ordinary stock and £1. 10s. per cent. on the preferred stock (less tax) payable 30th inst. After paying the foregoing dividends there will be a balance of £18,297 to be carried forward.

CENTRAL LONDON RAILWAY CO.—For the half-year ended June 30 a dividend of 3 per cent. per annum on the ordinary stock is recommended, and 4 per cent. per annum on the preferred. Provision is also made for the dividend on the deferred, payable at the end of the year, and £40,000 is carried forward. A year ago the dividends were at the same rate and £39,000 was carried forward.

CITY OF LONDON ELECTRIC LIGHTING CO. (LTD.)—The transfer books and register of members of this company will be closed from 27th inst. to Aug. 10 inclusive.

COUNTY OF LONDON ELECTRIC SUPPLY CO. (LTD.)—The directors have declared an interim dividend on the preference shares at the rate of 6 per cent. per annum (less tax) for the half-year ended June 30, and an interim dividend on the ordinary shares for the same period at the rate of 4 per cent. per annum (less tax), both payable on Aug. 2. The transfer books and register of members will be closed from 20th inst. to Aug. 2.

METALITE LIMITED.—We set out on another page an abridged prospectus of Metalite Limited. The capital is £500,000 in £1 shares of which 380,000 will be offered for subscription. The subscription list opens on Monday next, and will close on Friday, July 29, for London, and Saturday, July 30, for the country. The company has been formed to acquire as going concerns the "British Metalite" lamp and metallic filament manufacturing business in the United Kingdom of the Bryant Trading Synd., (Ltd.), and the business, patents, processes and goodwill of International Filaments, Limited. As regards price and efficiency, it is claimed for the "British Metalite" lamps that they are superior to any of the foreign productions sold in this country. The prospectus states that contracts at a substantial profit and exceeding fifteen million (15,000,000) filaments per annum for the next five years are already in hand and in course of execution, in addition to many large trade orders.

METROPOLITAN RAILWAY CO.—The directors recommend a dividend on the ordinary stock for the past half-year at the rate of 1½ per cent. per annum (against 1 per cent. last year), carrying forward about £6,000 (against £4,000), after placing £10,000 to electrical renewal and depreciation fund. The total receipts for the half-year were £391,488 and the expenses £194,019, leaving a profit of £197,468. The receipts show an increase of £12,001 and the expenses an increase of £776 over the corresponding half-year. The net revenue account, after providing for interest on debenture stocks and other fixed charges and placing £10,000 to electrical renewal and depreciation fund, showed a balance of £146,379.

ST. JAMES' & PALL MALL ELECTRIC LIGHT CO. (LTD.)—The directors have declared an interim dividend on the preference shares at the rate of 7 per cent. and on the ordinary shares at the rate of 10 per cent. for the half-year ended June 30. The share transfer books will be closed from July 23 to Aug. 5 inclusive.

A.C. Motor Starters.

IN these days of the wide application of motors to all kinds of industrial work, care has to be taken that the plant employed is in all cases suitable for the work it has to do. This condition is highly essential where starters are concerned, for they may be called upon to operate in textile factories, saw mills or other dusty places. They must therefore be suitably protected and must be so arranged that they can be worked wholly from the outside.

Mr. George Ellison, of Birmingham, has designed a series of starters with totally-enclosed covers and fitted with an inspection window and conduit caps. The arrangement of the double handle, with pointer and position marked on the cover, renders the operation of the starters most convenient, and there is no destructive burning of the contacts. The starters are fitted with a small external lever for tripping the retaining hook by hand, and as the starter arm has spring return to the "off" position, quick break action is obtained for stopping the motor. With this type of total enclosure, it is claimed that, it is impossible to touch live parts or terminals, and as the starters have no-voltage and overload releases the Home Office Rules and Regulations are entirely complied with. These starters are fitted with a patent combination of one no-volt coil connected across one of the stator phases and one overload coil connected in the rotor of slip ring motors (if the motor is not fitted with brush lifting and short-circuiting device for the slip rings), or in the stator circuit if the motor is of the "squirrel cage" type. This patent combination of one no-volt and one overload coil is, Mr. Ellison thinks, the only practical solution of the problem of protection for polyphase motors against failure of the supply on all or any one phase of the circuit.

The standard overload release is adjustable between 90 per cent. of the normal full load and 60 per cent. overload. As the overload coil is not in circuit until the running position is attained, it can be set for small overloads.

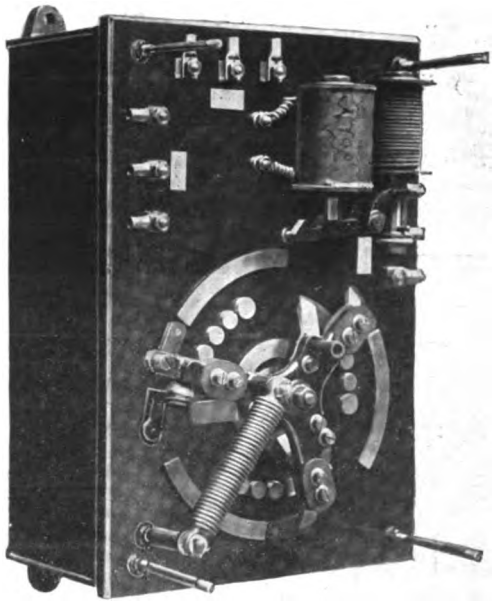

Fig. 1.—Double Automatic Release Starter controlling Stator and Rotor Circuits.

Of course, if the starting load is heavy and the operator puts the starter over to the running position too quickly, the overload release may operate if set for a small overload, and prevent the starter arm holding in the running position; the overload release will then have to be set for a heavier overload, or a patent adjustable time lag must be fitted. These retarders or time lags are particularly

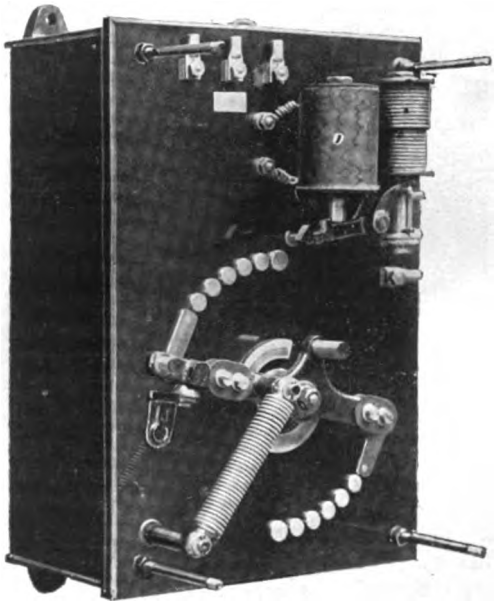

Fig. 2.—Double Automatic Release Starter.

recommended as an excellent addition to these starters where the conditions of service are such that the starting load is heavy or the running load a fluctuating one, subject to heavy peaks. The no-volt release can be utilised for stopping the motor at a distance by means of emergency switches so arranged that the no-volt coil circuit is opened

Digitized by Google

when it is desired to stop the motor. Totally enclosed starters of this type, with overload and no-voltage release, can be supplied for almost all types of alternating-current motors.

Fig. 1 shows a type of double automatic release starters which control the stator as well as the rotor circuits, so that a separate switch and fuses are not necessary. The overload coil being connected in the rotor circuit and the no-voltage coil across one of the stator phases, protection is given against overload and against no voltage on all or any one phase. If the motor has brush lifting and short-circuiting device for slip rings, the overload release can be suitably arranged to allow for this. The starters are suitable for three-phase and two-phase three-wire slip-ring motors, and for two-phase four-wire motors if one lead is taken direct to motor, the other three through the starter. In the type "B" double automatic release starters the rotor circuit only is controlled, so that a separate switch and fuses or circuit-breaker are required for controlling the stator circuits of the motor. The overload coil being connected in the rotor circuit and the no-voltage coil across one of the stator phases, protection is given against overload and against no voltage on all or any one phase. These starters are only suitable for motors that are not fitted with brush-lifting and short-circuiting devices for the slip rings.

Type "C" double automatic release starters are fitted with resistances for reducing the current taken from the line on starting squirrel-cage motor. They are suitable for starting against light load; the resistances (one minute rating) being proportioned to pass about twice full load current on the first contact, good makes of squirrel-cage motors will develop about half torque with this current. As the overload coil is only in circuit in the "full on" or running position it can be set for small overloads, if a certain amount of care is exercised in starting up. However, as the operator is not always able to judge whether the motor is sufficiently up to speed, the release (if set for small overloads) may operate and prevent the starter arm holding when the running position is attained. For this reason a time lag is an excellent addition, especially in cases where the running load is a fluctuating one, subject to heavy peaks. These starters control the three phases of the circuit; a separate switch and fuses or circuit-breaker is not required.

Fig. 2 shows the "D" type double automatic release starters. These are fitted with resistances for reducing the current taken from the line on starting up squirrel-cage motors. They are suitable for starting against light load, the resistances (one minute rating) being proportioned to pass about twice full load current on the first contact; good makes of squirrel cage motors will develop about half torque with this current. As the overload coil is only in circuit in the "full on" or running position it can be set for small overloads, if a certain amount of care is exercised in starting up. However, as the operator is not always able to judge whether the motor is sufficiently up to speed, the release (if set for small overloads) may operate, and prevent the starter arm holding when the running position is attained. For this reason a time lag is an excellent addition, especially where the running load is a fluctuating one, subject to heavy peaks. These starters control only two wires of the two-phase circuit, and a separate switch is required. However, for two-phase three-wire circuits, the starters can be arranged to control all three wires, thus avoiding the necessity of a separate switch.

These starters are, we understand, now being used extensively in the Midland factories, one firm having already over 800 H.P. installed. Mr. Ellison points out that his starters are quite "fool-proof," and should be eminently suitable for use where female labour is employed. This is an ungallant remark!

Electrical Operation of a Gas Works.

According to the "Light Railway and Tramway Journal," the new works, at Landy, of the Paris Gas Co., have been completed recently, and have been equipped with the most modern electrical appliances by the French Thomson-Houston Co.

These works are composed of three principal parts, each 25 ft. wide. The central part is 150 ft. long and 160 ft. wide. It contains the boilers, and on either side of it is a machinery hall, 150 ft. long by 50 ft. wide. There are two chimney stacks for the boiler furnaces. Fuel is brought in and the ashes are removed by means of a conveyor, the pipe work being in a basement under the floor level.

The two machinery halls are quite identical in equipment, save that in one of them foundations have been provided for a converter set, in case the works should be connected up to a source supplying alternating current, and that in the other hall there has been installed a booster for the battery of accumulators. Each generating set comprises a horizontal compound tandem steam engine of 650 H.P. indicated, direct-coupled to a continuous-current dynamo, of the compound excitation type, of 400 kw., 250 volts, 125 revs. per min. The flywheel is so fixed that the regulator prevents, in case of the sudden suppression of the full load, the number of revolutions from exceeding more than 5 per cent. above the normal. Under all conditions of load the relation between the extreme values of the angular speed during a revolution does not exceed $\frac{1}{150}$th of the average speed during such revolution. The switchboard in each hall consists of two superimposed series of panels, the lower being on the floor level and the upper level with a metal bridge or gallery. There are six panels in the lower and 12 panels in the upper board. These are fitted with the usual switches, circuit-breakers, and measuring, &c., instruments. Each hall is equipped with two generating sets and a motor generator, consisting of a continuous-current shunt-wound motor running at 600 revs. per min. and giving 125 H.P. at 250 volts, and a direct-coupled dynamo with two commutators, which can be grouped in series or in parallel, and each capable of furnishing normally a current of 1,200 amperes.

The current is transmitted to the different parts of the gas works by 10 overhead lines. No. 1 feeder serves the coke department, No. 2 the purifying house, Nos. 3, 4, 5 and 6 serve the distilling house, No. 1, and Nos. 7, 8, 9 and 10 the distilling house No. 2. All the feeders are doubled near the front of the building, and run into each of the two works, so that they can be connected up by means of the feeder panels, corresponding to the two series of 'bus-bars, in such a way that any of the feeders can be served by either of the works. Special connections also allow of the putting in parallel of the 'bus-bars of works No. 1 with those of works No. 2. The outer feeders are all of copper cables.

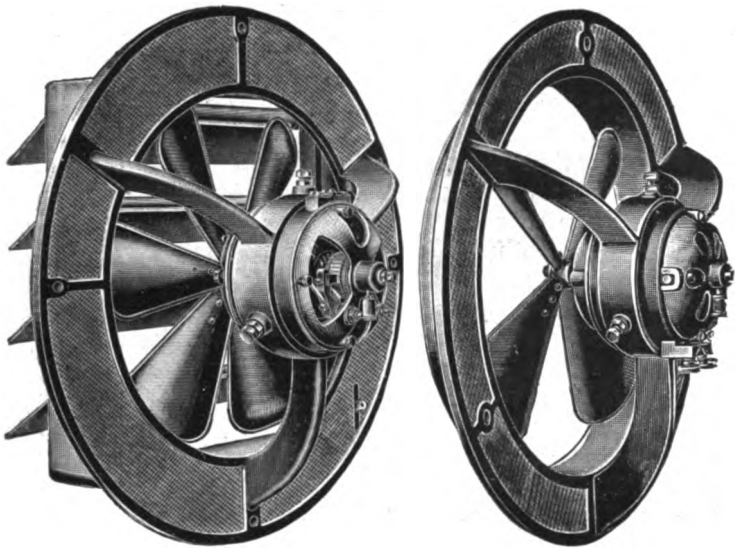
Digitized by Google

Inside the works the feeders are rubber insulated, and are carried to panels with circuit-breakers for each group of motors in such a fashion that they can instantly cut out any motor or group of motors in case of necessity.

Siemens Porthole Fans.

MESSRS. Siemens Bros. Dynamo Works are now manufacturing porthole fans for continuous, single-phase and three-phase current. These are normally arranged for a clockwise direction of rotation, though they can be arranged for running the other way or for reversing, if required. They can also be supplied with vertical shafts.

Fans fitted with continuous-current motors are made in nine sizes with a blade diameter varying from 10 in. to 32 in. and can be provided with either a protected or totally enclosed type of motor depending on the situation.



Figs. 1 and 2.—Examples of Siemens Porthole Fans.

Fig. 1 shows a standard type of porthole fan which can be fitted with any variety of motor, while Fig. 2 shows another type which is fitted with a venetian shutter that can be closed or opened as desired.

Porthole fans can also be fitted with single-phase or three-phase motors in similar sizes to those mentioned above in the case of continuous current. Single phase fans can, if desired, be run off the three-phase supply, while speed regulating devices are also provided when required. In the case of three-phase motors a throw-over switch is used for starting.

Asbestos Woven Net Resistances.

THIS is essentially an age of details, and it is therefore not surprising to find that great care is being taken in the perfection of each part of an apparatus so that the resulting whole may be as efficient as possible. In applying these remarks there is no direction in which they can be better turned than to the material used in building up the resistances required for motor starters and controllers. The material used for this purpose shows a great variety, and the most important are nickeline, constantan, rheostatine, excelsior, and others. There are very many different ways of making units for rheostats, the most common form adopted for the older types of motor starters and controllers, is resistance wire wound in spirals. Following is a description of a type of rheostat made by C. Schniewindt, of Neuenrade, which, it is claimed, has many advantages in comparison to the spirals just mentioned. The resistance is made by weaving asbestos threads and wires together, and the number of different forms this type of resistance can take is very large, and it can be applied to numerous purposes.

The following are claimed to be the advantages of this system: Small space required, convenient and cheap to mount, excellent insulation, and unbreakable through vibrations.

To illustrate the great adaptability in making up units to complete rheostats, let us follow the construction of a starting resistance for a 3 H.P. continuous-current motor for 110 volts arranged to start at full load. The starter is to be fitted with asbestos woven net resistances, an existing net 6 in. square being used for this purpose. The net has 25 wires, each with a diameter of 0·45 mm., and there are eight branch connections arranged in a geometrical row. One of these nets is sufficient for a starter for starting a ½ H.P. continuous-current motor for 110 volts at full load. Each resistance net weighs 45 grammes. By connecting

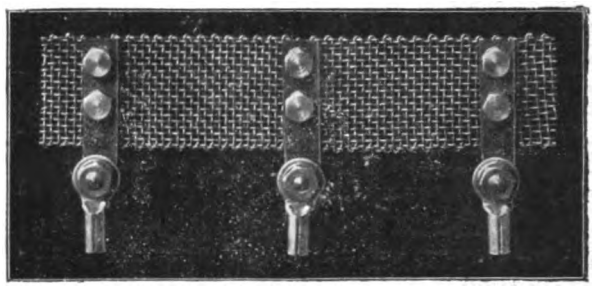


Fig. 1.—Asbestos Woven Resistance, showing Method of fixing Terminals.

six resistance nets as required for a ½ H.P. continuous-current motor in parallel, we get the total starting resistance for a 3 H.P. motor. Four resistance nets connected up in a similar manner are sufficient for a 2 H.P. motor. By this means the manufacturing process of motor starters, &c., becomes very cheap and simple, because one can easily use the same case for any number of motors of different sizes by connecting up resistance nets as required.

Compared with wire spirals the mounting of resistance nets is also very much simplified. The six nets for the 3 H.P. motor starter are built up together, one or two holes being punched in the sides of each resistance net. The portion free from wires is reserved for fixing purposes. They are then strung up on two or four bolts with a gap of about ¼ in. left between the adjacent nets. These gaps are packed up with strips of asbestos which are just as wide as the fixing portion at the sides of the resistance nets. Over the sides of the top and bottom nets there are narrow strips of iron, about ¾ in. wide, or the same width as the fixing portion of the nets, by which all the resistance nets are pressed together. It is also advisable to place a strip of mica between each iron strip and the first and last resistance nets, also to insulate the wire connections between each net with glass beads as illustrated in Fig. 1.

Digitized by Google

The bolts mentioned are also used for attaching the complete resistance to the contact plate.

In the case of spiral coils an insulating plate is used at the top and bottom for fixing the spirals. Another piece of insulating material is passed through the centre in order to prevent the spirals bending and touching one another when the load is on; this might happen owing to any vibration. These end pieces and intermediate pieces are a disadvantage of this design, because slate is mostly used which cracks easily when drilling large holes. The intermediate pieces also prevent the circulation of air, apart from the fact that this construction is more expensive and elaborate than that with asbestos woven net resistances with less bolts and holes. With spiral resistances the resistance steps cannot be arranged in such a manner that the motor can start without jerks, because the only point where proper branch connections to the contacts can be attached to is at the top end of each spiral. For the last steps of the starter it is, however, necessary to have an accurate and fine graduation, the resistance on the last step, for instance, should be less than that of the armature

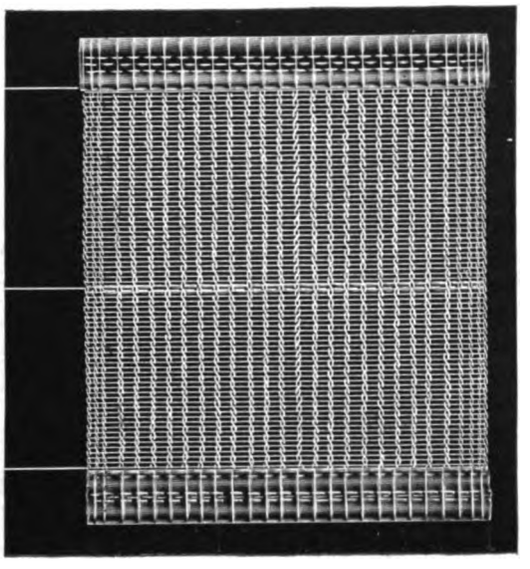

Fig. 3.

if the motor requires to be fully started without causing an appreciable rush of current. With resistance nets the disadvantage mentioned is not known, because one can obtain the required steps with great accuracy.

This comparison further shows that cheap labour can be employed for mounting and fixing this type of resistance, whereas spiral resistances can only be made up and connected by skilled and trained men, spiral wires of different sizes being used, the connecting up of which necessitates skilled and neat workmanship.

Numerous tests for ascertaining the temperature rise of asbestos woven net resistances have proved the astonishing rapidity with which the resistance nets cool after the current is switched off, this is a very important matter for apparatus for frequent starting. The permissible load, especially on starters, can therefore be comparatively high, provided the construction of the case will permit the circulation of air. The net resistances are also totally unaffected by continual heating and cooling, are thus suitable for changeable or any atmosphere.

The great stability of the resistance nets is a great advantage for resistances used in connection with shunt regulators, &c., the very thin wires required do not in the least reduce the rigidity.

Thin resistance wires wound in spirals are easily deformed, and it has often been found that this has caused damage to the regulator.

Other common designs for resistances consist, for instance, of porcelain cylinders with grooves threaded on, or rods with porcelain reels, but the advantages are all on the side of net resistances the mounting of which is much cheaper than that with other types of resistances.

The fact that asbestos units are unbreakable is a great advantage for crane and tramway controllers, which are subjected to violent vibrations.

Numerous experiments and tests have proved that these asbestos woven nets form the most suitable heating elements for the convector type of electric heaters, possessing many

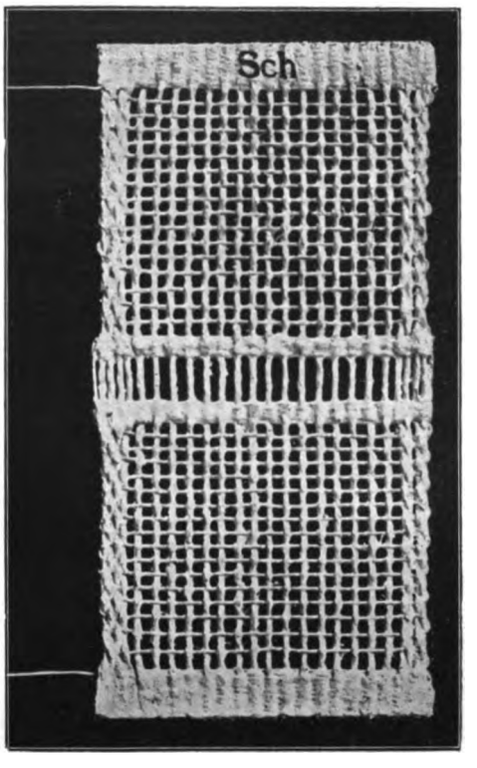

Fig. 4.

similar advantages as in the case of resistances. The radiator nets are installed in parallel, the number used being according to the heating capacity required. There is practically no self-induction, and the nets cannot be destroyed by vibration, and owing to the fact that they are manufactured only with the best materials, they will work with every satisfaction and without the slightest deterioration in heating capacity, for a long number of years, thus proving them to be the most economical and reliable heating elements. Further advantages of these heating nets are the small amount of space the units take up when assembled, and the remarkable lightness they possess, which makes them the most suitable heating elements adaptable for the light semi-portable electric heaters which are at present in demand. The accompanying illustrations show examples of asbestos woven net resistances.

Electrically-Driven Pumps in Mines.

THE more the miner goes towards the centre of the earth, the greater are the risks he runs of encountering large quantities of water. The economical removal of this water is therefore one of the greatest problems of mining work. To do this the low efficiency pumping engine, the slow running reciprocating pump and electrically-driven high pressure centrifugal pump have all been used.

While the two first kinds of pump have the disadvantage of small reliability it was further always impossible to use steam driven pumps underground to any great extent, owing to the warming of the shaft, large condensing losses, and the great space required by the steam machinery and piping. It is for these reasons that the electrically-driven pump has come so much to the fore for mining work.

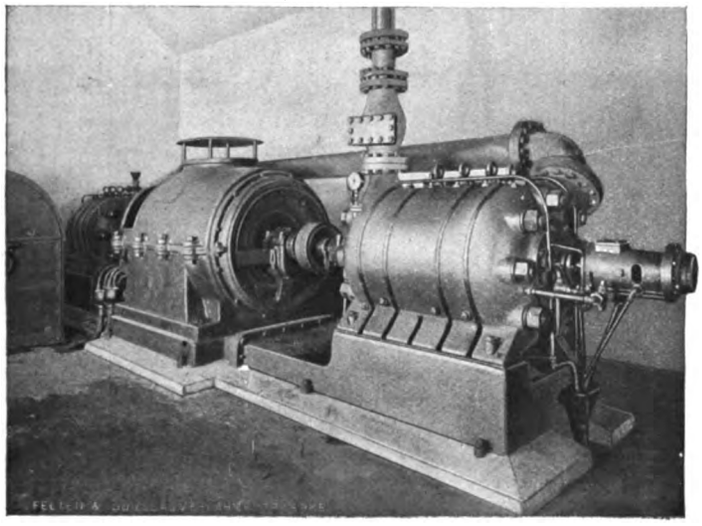

Fig. 1.—Pump Installation at the Antonienhutte.

A firm which has had a good deal to do with the development of this class of machinery is the Felten & Guilleaume-Lahmeyerwerke A.G. who, as long ago as 1897, erected an electrically-driven pump for unwatering purposes in the Zollverein mine at Caternberg in Westphalia. This pump was operated by a slow running 320 H.P. three-phase motor. Soon after a large number of similar electrically-driven pumps were supplied to several other mines.

A further step forward was made when so-called express pumps were adopted, running at about 300 revs. per min. These had the advantages of taking up a small space, and making it, therefore, possible to take them right down into the mine. It should, however, be noted that this speed was not very suitable for large pumps. The high speed high pressure centrifugal pump direct coupled to an electric motor was the first possible, and almost ideal, solution of the unwatering problem in mines. Along with the adoption of this class of plant may be seen the development of modern machinery for high speed work, and the attempt to reduce the amount of material used, especially in the moving parts, for large outputs. Where the use of electrical energy is possible, and the water does not make a continuous use of the pump necessary, electrically-driven high-pressure centrifugal pumps are mostly employed at the present time. On account of the high speed and the direct coupling between the pump and the motor a very compact combined arrangement is obtained, so that a cheap pump chamber in the mine itself can be erected. The transport of material down the shaft and along the stulms is quite easy, while the erection underground is very much simplified when compared with that of the slow speed machine. Finally a simple and cheap operation, on account of the small wear in moving parts, is obtained with such machinery.

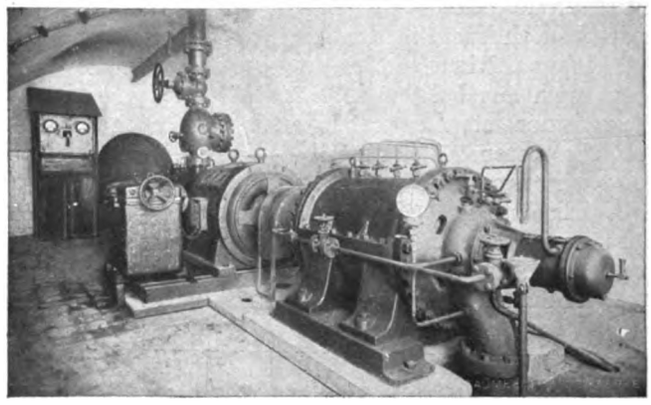

Fig. 2.—One of the Turbine Pumps at the Velsen Mine.

Fig. 1 shows the underground installation at Antonienhütte. This consists of two high pressure centrifugal pumps, which each deliver 6 cubic meters of water per minute to a height of 500 m., they are coupled to a three-phase motor with a capacity of 1,000 H.P. when running at 1,230 revs. per min. The working voltage of the motor, which is fitted with a short circuiting and brush lifting arrangement, is 2,000 volts. On account of the small dimensions of the shaft it was necessary to build the stator in two parts. A liquid starter is used in connection with this set.

Fig. 2 shows an underground pumping installation at the Royal Velsen mines. It consists of two six-stage turbine pumps direct coupled to an electric motor. By means of this installation about 2 cubic metres of water can be delivered to a height of 475 metres per minute. The motor is of the short-circuited type, and has a capacity of 350 H.P., when running at 1,500 revs. per min. The voltage is 5,000

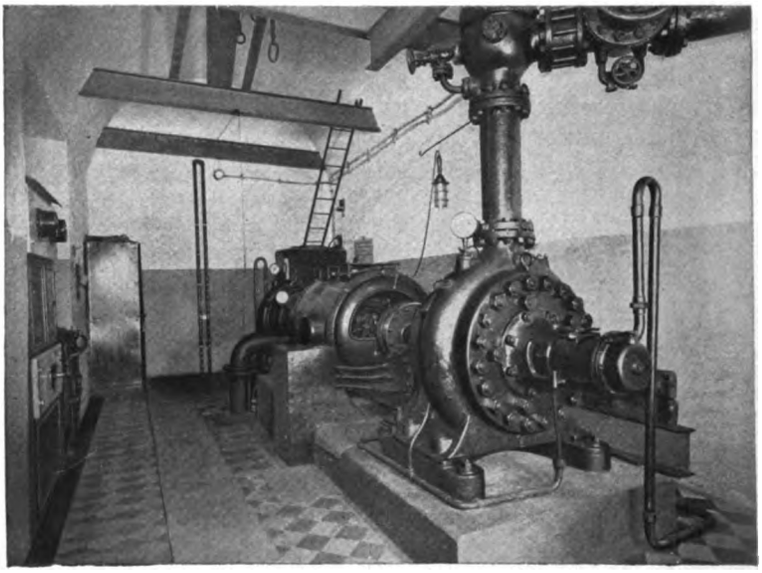

Fig 3.—Electrically-driven Unwatering Plant at Mont Cenis.

Digitized by Google

and the starting is effected by means of a transformer arrangement, which can be seen in the illustration. Attention may be called to the small dimensions and weight of the driving motor. Its greatest length is 1,450 mm., the maximum width 1,150 mm., its greatest height from the

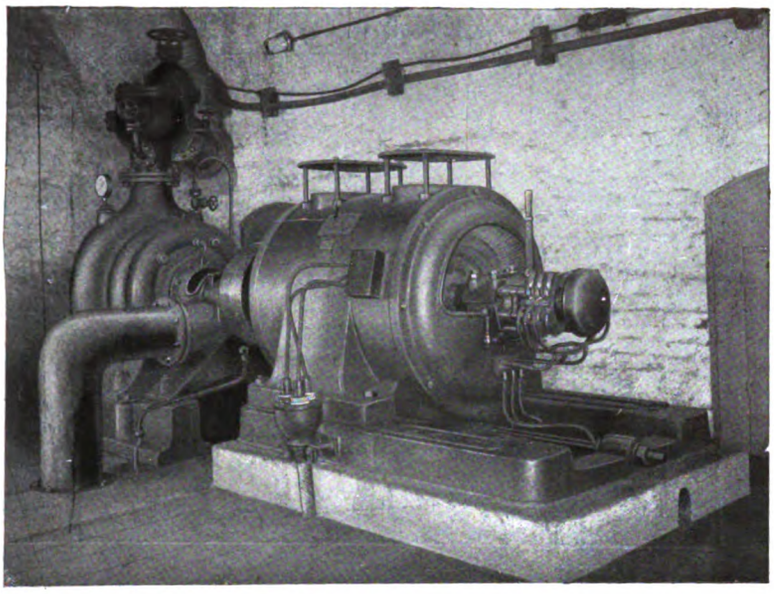

Fig. 4.—Pumps at the Massener Tiefbau Mine.

rails being 1,210 mm. The total weight of the motor is just over 3 tons. If these figures are compared with a slow running electric motor or a steam engine of the same output, the advantages of fast running electric working for unwatering purposes are manifest, while attention may also be called to the greater ease in bringing the material down the shaft and the small space taken up.

Fig. 3 shows an unwatering plant installed at the stone works at Mont Cenis. It consists of an asynchronous three-phase motor with a continuous output of 450 H.P. when

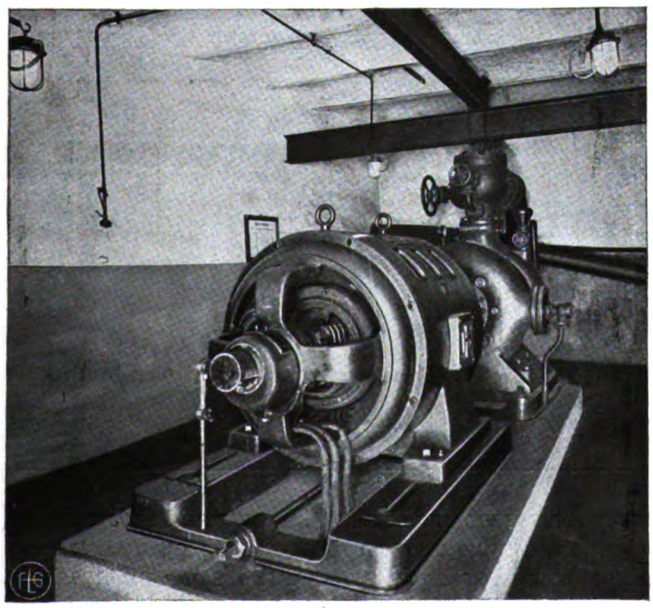

Fig. 5.—Pumping Installation driven by Three-phase Motors.

running at 1,475 revs. per min., the terminal voltage being 2,000. A liquid starter is used for the operation of this motor. Another asynchronous motor fitted with slip rings for a working voltage of 200 is shown in Fig. 4. This set is installed for unwatering purposes in the Massener Tiefbau mine, and when running at 1,475 revs. per min. and exerting horse-power of 470 can raise 5½ cubic metres of water a minute to a height of 267·5 metres. The construction of the two motors is similar to the standard construction of the Lahmeyer Co., adapted to high speed motors for large outputs and contains no special peculiarities. The diameter of both motors is 595 mm., so that the speed

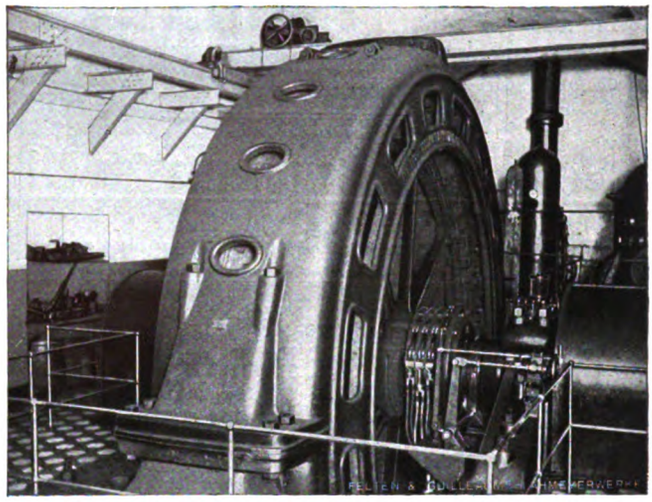

Fig. 6.—Slow-speed 2,500-volt Pump Motor.

of the armature works out at 46 meters per second. In order to move the motor in an axial direction, sliding rails are provided along which a motor can be shifted by means of a screw worked by a hand lever. Mention may be made of the plant at the Wildberg mine, which consists of two continuous current shunt wound motors, each with an output of 175 H.P. Their speed can be regulated between 416 and 715 revs. per min. They drive two high-pressure centrifugal pumps, and deliver 1·5 cubic metres to a height of 230 metres, running at the lower speed, and to the height of 316 metres at the higher speed.

In connection with the construction of these motors, it may be noticed that the armature iron is 250 mm. wide, and has a diameter of 480 mm., so that its peripheral speed when running at 715 revs. per min. is about 43 metres per second. The diameter of the commutator is kept as small as possible owing to the high speed, and being 250 mm., the peripheral speed works out at 22 metres a second. The commutator is secured by two shrunk rings, such as are used on the commutators of turbo-generators. For ventilation purposes a fan is placed on the motor to the opposite side of the com-

THE THOMSON ELECTRIC LAMP.

The Meter Reader's Lamp.

HANDSOME, DURABLE, NICKEL PLATED CASE. COMPACT, HANDY, AND PORTABLE IN SIZE.

The accumulator can easily be recharged, and will give from 4 to 6 hours' Brilliant and Continuous Light. For the past three years the THOMSON LAMP has been Used in all parts of the world, for all purposes.

mutator on all the Lahmeyer Co.'s high-speed three-phase motors, as shown in Fig. 5.

In mines, where the unwatering operations have to be continuous and the water dealt with is very large, a suitable efficiency is obtained by the use of slow running reciprocating pumps such as is shown in Fig. 6. The pump is of the double reciprocating type, and delivers 180 cubic metres a minute to a height of 620 metres. The driving motor is of the three-phase type fitted with slip rings and short circuiting arrangements. It is worked off a voltage of 2,500, the frequency being 50 and 75 revs. per min. At this speed the capacity of the motor is 1,300 H.P.

Portable Instruments for Direct and Alternating Currents.

MESSRS. Nalder Bros. & Thompson, of 34, Queen-street, London, E.C., have recently placed upon the market a complete line of portable standard instruments, suitable for continuous and alternating currents. These instruments are of the dynamometer type, and are fitted with air damping to render them dead beat. They have been carefully designed with a view

Fig. 1.—Portable Standard Voltmeter.

to giving great accuracy on either continuous or alternating-current circuits. The instruments have been thoroughly tested under all the varying conditions met with in practice, and give the most satisfactory results.

Instruments of this type comprise ammeters, voltmeters and wattmeters, they are fitted in portable polished wood cases with strap handle, lock and key, the cases being protected with rubber feet (which ensure that no sudden jar shall be received whilst the instrument is in use) and are arranged with anti-parallax mirror. The pointers are of the edgewise pattern, and the scales are very finely and accurately divided, so that observations can be taken with a considerable degree of accuracy. It will be noticed that the instruments are supplied with a zero adjustment, so that in the event of any slight variation in the zero it can be set quickly and easily.

One of the features of these instruments is that they can be made multi-range, thus the portable standard voltmeter illustrated, shows ranges of 15, 150 and 600 volts (*see* Fig. 1.) The ammeters are wound self-contained for currents up to 50 amperes, beyond which portable series transformers are supplied. The wattmeters are arranged self-contained for pressures up to 300 volts, and currents up to 50 amperes. For pressures over 300 and up to 650 volts, an external resistance box is used and for currents above 50 amperes portable series transformers, as in the case of the ammeters. For high tension circuits potential and series transformers are employed.

Fig. 2 illustrates the portable standard wattmeter, the instrument described is self-contained for circuit voltage up to 150 volts and not exceeding 20 amperes. Another

Fig. 2.—Portable Standard Wattmeter.

instrument suitable for continuous and alternating currents, and constructed on the dynamometer principle, is the lamp-testing wattmeter, shown in Fig. 3. This instrument is arranged for two voltages, say, 100 or 200 volts, and with a two-way switch key which, when placed on the contact corresponding to the voltage required, is depressed and an indication on the instrument obtained, the instrument reading directly the actual watts consumed. The instrument is fitted in polished wood case with strap handle, and one side carries the lamp-holder and fuse, and is equipped with a length of flexible wire fitted to a plug,

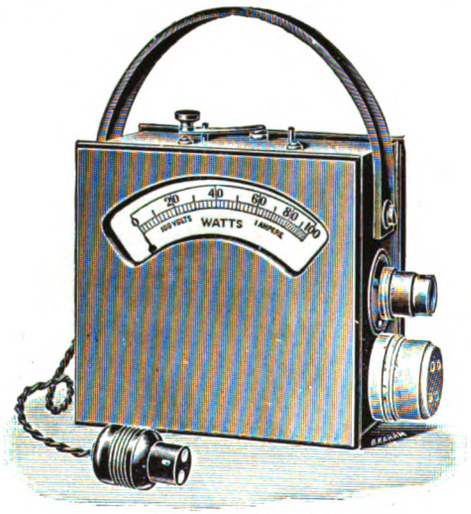

Fig. 3.—Lamp Testing Wattmeter.

which can be inserted into the standard lamp-holders. The dynamometer type of dead-beat instrument is also made in switchboard pattern case, black enamelled and nickel or copper finish.

In the construction of their instruments, we understand, Messrs. Nalder Bros. & Thompson make a very strong point of the fact that they use only English material, and strictly exclude everything of foreign origin, excepting, of course, such material as is not obtainable in this country.

High-Tension Switchgear for Mines.

IN view of the necessity for switchgear which is absolutely safe for use in coal mines, and which complies with the Home Office Regulations, the Union Electric Co. has now designed an improved oil-break switch, which embodies the principal features of the Union exclusive designs in oil-break switches with automatic features and oil-break switches combined with fuses. This switch is the result of many experiments and tests carried out under actual working conditions and extending over a long period. The terminals of the incoming and outgoing cables are arranged in a special manner, the terminals being protected by either cast or wrought-iron enclosures. In addition to securing absolute protection for the cables against mechanical damage, the design lends itself to exceedingly simple methods of building up the switch units to form complete switches and distribution boards, with other advantages, such as ease of erection in connecting up and effective operation. There is also a very simple method of re-setting the overload release.

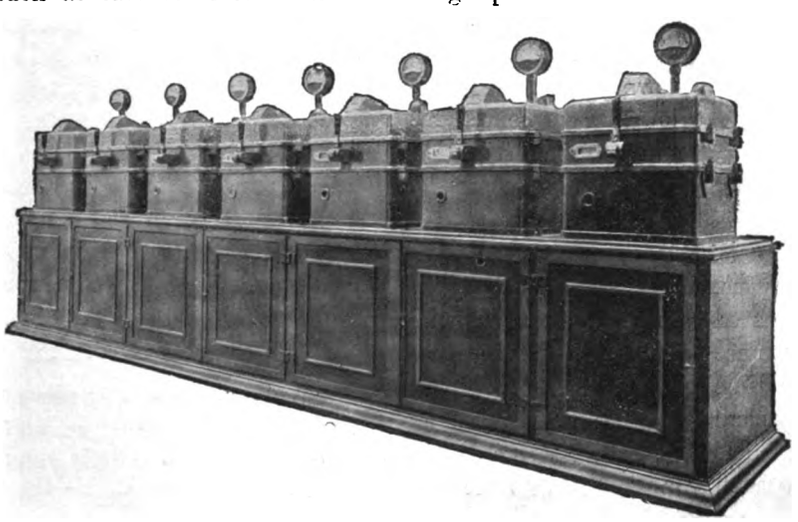

Fig. 1.—Mining Switchboard.

These switches are made in two designs, one for mounting on an angle-iron framework or stonework cells and the other for fixing to floors. In the latter type, on the assumption that the switch will be placed with its back against a wall or against the 'bus-bar enclosure, an opening is provided in the sheet-iron casing at the back. The space under the switch is accessible from the front, which is fitted with a detachable panel provided with a lock. Externally the switch consists of three parts: the lower case or oil tank, in the bottom of which are fitted the contacts and terminals; a centre casting on which is mounted the switch mechanism; and the cover enclosing the whole apparatus. This cover is provided with a special form of relief valve with flame-proof cap. It is, therefore, possible for the whole of the moving parts of the switch to be removed for inspection without disturbing any of the cable connections. The switch is fitted with two overload releases with the release coils immersed in oil, therefore the expense and extra complication in the connections incurred by the use of current transformers are obviated. The moving element of the switch is operated in the usual manner by a hand lever with independent release gear to prevent the switch being put in against an overload. An indicating arrangement, showing the position of the switch, is fixed in a conspicuous position on the case. There is also fitted a contact device for operating red and green signal lamps. The overload releases are adjusted by a key, and a scale with movable pointer shows the exact value in amperes at which the release will come into operation.

In connection with the overload release the switch can be fitted with a simple mechanical time element with adjustable time lag. This can be arranged to release the trip mechanism in from 2 to 7 seconds, the period not being dependent upon the value of the overload. This possesses great advantages in cases where several switches are in use in connection with one another and with the main supply, as the elements can be arranged to trip the switches in a certain predetermined sequence. To secure absolute safety against damage in the case of short-circuits provision is made to ensure an instantaneous trip when the overload reaches the value of approximately four times that of the maximum releasing overload for which the switch is intended. This combination of definite time lag for ordinary overloads and instantaneous release on short-circuits possesses advantages which will be appreciated by all engineers. In connection with the time element a second dial is provided with a pointer which indicates how often an overload has occurred which has passed off before the time limit has expired, and therefore without tripping the switch.

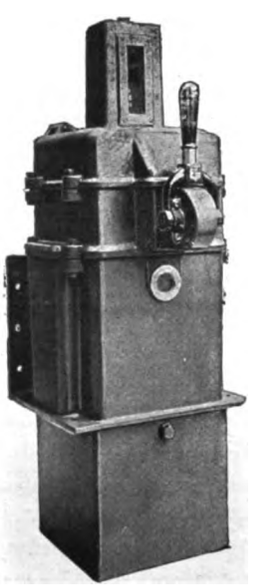

Fig. 2.—Union Mining Switch Unit.

A no-volt release attachment can be provided, and the coils wound for pressures up to 600 volts. In the case of high-tension circuits, suitable pressure transformers are required in connection, and in these cases the terminals of the no-volt coil are brought to the outside of the case by means of a water-tight receptacle with plug. Where ammeters are supplied with the switches their current transformers are arranged within the switch cases and oil immersed.

For use in situations where the space available is very limited, the Union Electric Co. have designed an extremely compact switch suitable for pressures up to 3,000 volts. This is an oil-break switch with cast-iron flame-proof enclosure. It is provided with automatic overload releases on two phases, the release coils being adjustable from the outside of case. Suitable indicating devices are also provided to show the position of the switch. As the terminals for the incoming and outgoing cables are arranged in a special manner, the switches may be assembled upon a framework to form a complete distributing switchboard.

THE ELECTRICIAN INDUSTRIAL SUPPLEMENT

ISSUED MONTHLY — "THE ELECTRICIAN"

Telegraphic Address: "ELECTRICIAN NEWSPAPER LONDON" Telephone No. 949 HOLBORN.

All communications should be addressed to the Editor, "The Electrician" Industrial Supplement, 1, 2 and 3, Salisbury Court, Fleet Street, London, E.C.

Copy for Text or Advertisement pages for next issue, publishing on **August 19th, 1910,** *should reach the above address by Tuesday,* **August 9th, 1910.**

Manufacturers, Contractors, Central Station Engineers, and those interested in Electrical Industrial Developments are cordially invited to contribute original matter to the SUPPLEMENT, and when suitable this will be inserted as space permits.

Filing Case for "The Electrician" Industrial Supplement.

The INDUSTRIAL SUPPLEMENT is holed for filing, and we are distributing cases which will hold twelve issues. On request a case will be sent to Consulting, Manufacturing, or Contracting firms; to Chief or Resident Engineers of Electricity Supply, Traction or Power Stations; to any firm of Merchants or Agents; to Railway, Tramway, Dock, Harbour, or other companies interested in the applications of Electric Power, &c., to their undertakings; and to other large consumers of electrical energy, either at home, in the Colonies, or abroad.

A portion of each issue of the SUPPLEMENT is reserved for special circulation oversea.

Editorial.

Conservation Problems.

There are not wanting those among us, though, unfortunately, they are not treated as they deserve, who point out that we are wasting our national and natural resources, and that a time will come, unless we speedily mend our ways, when we shall be bankrupt in this way at any rate. Anyone who has considered this subject at all will agree that there is much truth in these contentions. Not only do we waste what we have got, as can be easily gathered any day in manufacturing districts, but we take no thought for the future or consider any proposals for preventing the total loss of our natural resources. Coal, perhaps our most valuable commodity, is wasted in large quantities every day, while much is recklessly shipped abroad. It should not be forgotten in this connection that while the supplies of coal are large they are not unlimited, and that once the present deposits are worked out, which may not occur for years, but certainly will occur in time, this country will be in a difficult position. Much of our prosperity has been and is dependent on our coal supply, and every means should be therefore taken carefully to preserve it to our own use. The absence of water power in these islands makes this warning all the more necessary.

But even where water power is available it is altogether a wrong policy to waste it. Even that supply is not illimitable, and to make it continuously available requires careful handling. Indeed, Mr. L. Stillwell, president of the American Institute of Electrical Engineers, in a recent address, pointed out that great care must be taken in order that the water power shall not fall off. He contends that government control should be exercised over such falls as are not appropriated and should determine how and when they may be utilised. If this is not done the water power will speedily be exhausted and the country's natural assets will be that much the poorer. There are certain difficulties in determining how power users should be taxed, but the benefits which the general public must derive therefrom far outweigh these. It is time that this matter was taken up strongly, and that we as engineers should demand that some control be placed over the use of our coal supplies, which are, after all, national property.

The Extension of Supply from Continuous-current Stations.

In designing anything of an engineering nature which is to be used by the general public, the factor which is by far the hardest to determine is that of expansion. It is exceedingly difficult to determine whether a certain width of road will be adequate for the traffic 25 years hence or whether the passengers that will depart from a certain station 10 years hence will be able to use the present platforms without overcrowding. In the same way electrical engineers are faced with the problem of the expanding area of the towns they have to supply. Fifteen years ago a system of low-tension continuous current seemed quite the right thing to use for providing the town with light. But to-day with a large power load and an ever-widening area the problem of how best to meet the demands on the stations is a stiff one. One way to overcome it is to lay down high-tension plant to supply the outlying areas and to continue to employ the older machines for the district nearer home. This solution is in many ways good, except for the difficulty of knowing just where to leave off supplying the continuous current direct from the generating station and to start supplying it through sub-stations. This can be overcome by "feeding back" into the nearer area from the sub-stations—that is, instead of separating up the whole area into two sections, to keep it as one, but to feed the outer part from three-phase plant. This rather obvious solution has, of course, been often employed both in this country and abroad.

In a recent issue of the "Elektrotechnischer Anzeiger," Mr. W. Fuhrmann describes a somewhat different solution. He proposes the use of three-wire dynamos. These are provided with slip rings as well as commutators, so that alternating energy can be tapped off and stepped up for transmission to the outlying districts. The exact idea of this arrangement is not very evident, and it has the disadvantages that frequency troubles are sure to arise, for either the alternating current will be too low a frequency or the continuous current will tend to fluctuate. The old arrangement is not ideal, but it seems to be the best that can be devised.

Sub-Station Economy.

In this country among a certain class of engineers the sub-station is looked upon as a place to which aspiring students may be relegated on leaving college. It is doubtless felt that if they can stand sub-station work they can stand anything. It is a sort of cleansing by fire. The wages bill for a sub-station is therefore not high, but the arrangement does not

make for great efficiency. If economy is to be practised on the wages account of a sub-station it must be effected by adding to rather than detracting from the duties of the attendant. Instead of allowing him to browse on penny dreadfuls during the whole of his shift, there is no reason, if the station be of the traction type, why he should not be employed on some traffic work, such as checking tickets or analysing reports. Similar work might be done in a lighting or power station. In this way a special man for this work would be saved, while the student would be acquiring useful knowledge instead of wasting his time. In dealing with this question the "Electrical World" states that in analysing the probable cost of operating a sub-station of, say, 500 kw. capacity in railway service, it appears that a good load factor is quite as important in relation to a low unit expense as in an ordinary generating plant. A recently completed sub-station of this capacity cost £4,400, including land, or £8. 16s. per kilowatt. Under reasonably favourable operating conditions the ratio of the average output to the normal capacity of the installation might be 30 per cent., giving a total yearly delivery of 1,315,000 kw.-hours at the continuous-current 'bus bars. Taking interest at 6 per cent., insurance and taxes 1 per cent. each, and depreciation 5 per cent., the fixed charges would reach £572 per year, or about 0·11d. per kilowatt-hour. In this installation three men are required, with wages totalling roughly 32s. per day. The labour cost, then, may be taken at about £564 per year, and allowing £156 for repairs and £80 for supplies, the total operating expenses reach £80. The total cost of handling the yearly service of the sub-station thus may be estimated at 0·26d. per unit of energy delivered to the continuous-current feeders.

These figures seem to show that the economy in operation is already as high as may be expected, but that something can be saved by careful design and on the wages account.

Electric Drive in the Machine Shop. The motor has for so long now been recognised as the proper machine to drive the tools and other apparatus used in an engineering shop that it is not surprising to find that useful information has been obtained on the best ways to arrange and drive the machinery, and that figures have been arrived at on which future work may be based. Perhaps the most important result of the general use of the motor is that machine-shop driving has become much more flexible than was formerly possible. Lathes or other machines can be placed conveniently for the work they have to do instead of having to be arranged with reference to the main shafting. The withdrawal of forests of belts allows greater facilities for handling materials both at the tools themselves and between them. The use of overhead cranes can be made much more extended, and as these will also be motor driven the use of ropes and other archaic plant is avoided. Further, a breakdown can much less seldom shut down the whole plant, while any breakdowns can be easily attributed to the proper quarter.

The London Showrooms of the General Electric Co.

THERE has been much talk of the decentralisation of showrooms, of the opening of shops in the main streets of both large and small towns, and the supply to the public direct by the central station engineer of every kind of electricity consuming device. As a result of these recommendations one might expect to find a tendency on the part of the large wholesale electrical houses to curtail the expenditure of their showrooms and the display of electrical apparatus. It appears that how-

Fig. 1.—A G.E.C. Pendant.

ever desirable it may be to appeal directly to the buying public in electrical matters, both trade and domestic, the large wholesale showroom is still a necessity.

A showroom to be successful must be arranged with the utmost care to admit of comfortable inspection of the apparatus and to avoid undue clashing of the various articles on view; the latter more particularly applies to the display of electrical fittings. An attractive well-balanced showroom will always bring business and good business at that. The Queen Victoria-street showrooms of the General Electric Co. may be said to attain to a high standard in the matters of selection, adornment and classified grouping of electrical apparatus. The company's familiar premises have been recently undergoing a process of enlargement, and many improvements have been effected though none appear to be so extensive or modern as those carried out in the showrooms. Of these latter there are two, one on the ground floor and the other on the first floor, and they are each sub-divided into sections which contain some special group of fittings or apparatus.

At this juncture we may remark that the General Electric Co. has a special department for the design of electric fittings of every description. Not only does this department deal with the ordinary patterns of fittings from which a large number will be struck off, but also it acts in an advisory capacity where designs in some special style are

Fig. 2.—G.E.C. Radiator.

required. For instance, the majority of our great public buildings are constructed in accordance with the plans of a special architect. In the illumination of these buildings it is impossible to introduce standard patterns of fittings such as might be met with in the large showroom of the General Electric Co. The matters of the design and style of the fittings for each particular building must be submitted to an expert, who will only adopt a particular form and grouping as a result of close study of the requirements

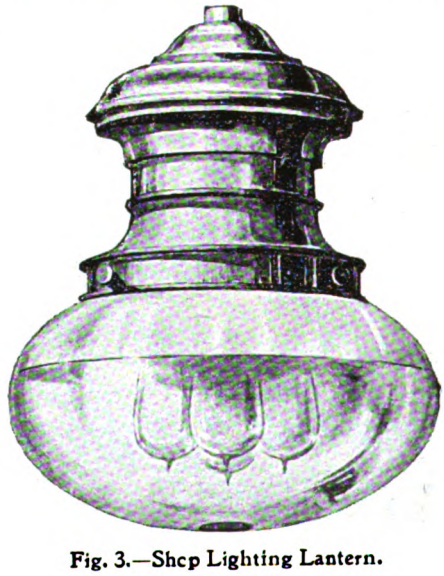

Fig. 3.—Shop Lighting Lantern.

of each individual case. The General Electric Co. has been and is regularly entrusted with important work of this character, and one has only to inspect its showrooms and turn over the pages of its fittings list to be at once impressed with the beauty and variety which are everywhere apparent in the results achieved.

Digitized by Google

A feature of the first floor showroom from a popular point of view is a special room set apart for the display of French fittings. It is interesting to note that the company's designs and manufactures in this direction are of such consistently good quality that they can successfully compete with the French models. Our attention was particularly directed to the real gilt patterns which are undoubtedly handsome and highly ornamental. Candle brackets which are replicas of the Grand Fontainebleau and Louis XIII., XIV., XV., and XVI. models were specially

Fig. 4.—G.E.C. Milk Heater.

noticeable. These fittings have all been appropriately grouped, and can be severally or collectively turned on for display purposes.

Another portion of the first floor showroom is devoted to a special line of crystal fittings, which, we understand, are in considerable demand at the present time. With these fittings very pretty lighting effects can be obtained, more especially with Osram lamps. The crystals screen the source of illumination from direct contact with the eye and at the same time act as useful light diffusers. These fittings are mainly suitable for suspension from the ceiling, and the majority of the designs shown are of this pattern.

In the same showroom there is a tasteful display of adjustable pendants, such as are now very popular for diningroom and bedroom use. The diningroom patterns are now usually surrounded with an annular shade which screens the direct light of the lamps from the eye but at the

Fig. 5.—Two-light Bracket.

same time admits of upward reflection to the ceiling, from which the light is thrown down into the room. Practically every taste and every pocket are catered for in this group of fittings; for instance, a flat furnished upon a modest scale can be provided with its tasteful pendant appropriately to harmonise with the surrounding decorations. These moderate priced fittings are in large demand and can be seen to the best possible advantage in the showroom.

Practically the only remaining corner in the first floor showroom is occupied with an important trade section. Electric signs and flashers of every conceivable pattern have been erected on the walls and special circuits are run to the lamps so that each sign can be shown under both day and night conditions. From the point of view of an electrical contractor, who has no special showroom, but who is anxious to do business with a local tradesman, this portion of the showroom is of great value. If he can persuade tradespeople to make a journey to Queen Victoria-street—not a very difficult matter—he can then make a selection from a large variety of signs. In this same corner has been arranged many of the new pattern lanterns for holding one or more Osram lamps. These lanterns are taking the place of the small arc lamp for the lighting of shop windows both inside and out, and also for the illumination of small spaces. They are displayed in a great

Fig. 6.—G.E.C. Glassware Electrolier.

variety of types from the humble pattern containing a single 50 c.p. Osram lamp to the more ambitious variety, with half-a-dozen 50 c.p. lamps or a single 500 c.p. lamp. These lanterns can also be turned on severally or collectively to give an idea of the illuminating effect.

In this same section may be demonstrated the practical value of "strip-lite," a form of G.E.C. reflecting tubular lamp which is most effective for shop windows, show cases, jewellers' display cases, museums and picture galleries. In its most recent form this reflected lighting system has a central double holder carrying two lamps, which are both partly surrounded by an adjustable reflector. This pattern of illuminant is of small size, being narrow and long, and therefore admirably adapted for attachment to ledges, beadings, shelves, &c.

The showroom on the ground floor is rather larger than the one upstairs, and contains such fittings as electroliers,

Digitized by Google

floor standards and special brackets. The electroliers and ceiling fittings are displayed in the centre of the room, and many of these are of very massive character. For instance, there is a particularly fine specimen in the shape of a bronze ceiling fitting, of which 400 were supplied to the Victoria and Albert Museum. This particular type is provided with a large bronze ring which is worked out of a single sheet of metal. A somewhat lighter pattern, but of similar design, which was supplied to the Victorian Government Strand building, is also on view.

This showroom is triangular in shape, and one of the longer sides is divided off into a number of compartments in each of which distinctive styles of fittings are displayed. There is a special bay for Dutch fittings, which contains many beautiful designs, and this will bear close inspection by buyers interested in these particular patterns. The range of floor standards in this room is very complete, and includes both the heavier and lighter designs. The radiator has received careful attention, and the General Electric Co. cater very widely for the radiator purchasing customer. There is a vast difference in price between the severe and the highly ornate in luminous radiators, and although the latter consumes not a watt less energy than the former the amount of work put in to its repoussé front or its richly chased sides is evidently worth paying for. The man who is blessed with an abundance of this world's goods and who is able to furnish various rooms in his house in accordance with particular styles can harmonise both the electric fittings and the electric radiator, not forgetting also the switches, bell pushes and wall plugs, with the adornments of the room. This class of customer is well catered for by the General Electric Co., and can have his every need satisfied.

A considerable portion of the ground floor showroom is devoted to a practical display of electric cooking apparatus. Here the latest patterns of G.E.C. ovens, hot plates, irons,

Fig. 7.—View of General Fittings Showroom at the General Electric Co.'s Head Office, 67, Queen Victoria Street, E.C.

fittings displayed are shown in polished brass, oxidised copper, oxidised silver, gilt and brass. Nearly the whole of one side of the showroom is occupied by a fine display of shades, so that a customer, after making a selection of a particular type of fitting, can choose a suitable series of shades. As in the case of the fittings in the showroom on the first floor, the ground floor showroom has been carefully wired so that any type of fitting selected can be immediately put in circuit.

Before we touch upon the electric cooking appliances which are given a special place in the showroom, we may say a word at this point on the subject of radiators. Most business men are familiar with the two-light or four-light luminous radiator which furnish heat upon hygienic lines in many modern commercial houses. For use in the home this welcome heater must present a less severe appearance than its office prototype. The production of an ornamental shaving water heaters, kettles, saucepans, steamers and numerous other forms of electric heating apparatus are on view. Practical demonstrations of the facility for quickly obtaining heat in cooking utensils, are regularly given, and consequently the prospective buyer is given an opportunity of judging of the suitability of the apparatus for his or her purpose. The attractive feature of this exhibit is an inexpensive oven which will cook a dinner for six or eight people at a cost of a few pence. Another interesting piece of apparatus is a toaster, which can be used on the breakfast table. The growing popularity of electric heating apparatus may be gathered from the fact that the company has supplied over 2,000 electric irons during the present season. One of the ovens on show is also fitted with a patent indicator which shows at what particular heating the oven is being used. It indicates whether the current has been left on or off.

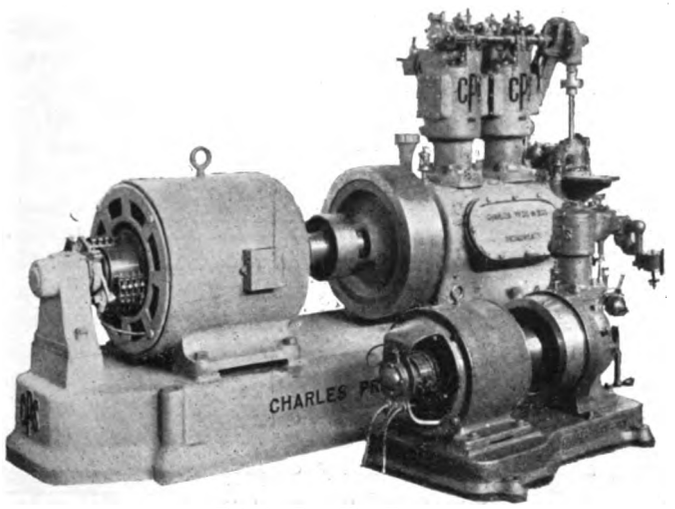
Price's Two-Cylinder Paraffin-Electric Set.

AN interesting paraffin-electric set made by Messrs. Chas. Price & Son, of Manchester, consists of a two-cylinder engine of 19 B.H.P. direct coupled to a 9·9 kw. shunt-wound dynamo. The engine is built to run on cheap petroleum oil (6d. to 6½d. per gallon), a perfectly clear and odourless exhaust being obtained when using fuel of this quality.

The crank shaft and valve operating mechanism is situated above the cylinder, the valve tappets being adjustable for wear; while the valves are contained in cast-iron cases and held in position by forged clips. The cams are hardened, and operate the valve rocking lever through the medium of hardened rollers running on hardened pins; half compression gear is fitted to ease the starting. Ignition is effected by means of a high-tension magneto, with a supplementary system consisting of a synchronised coil and accumulator. Lubrication is forced through the crank-shaft bearings by



Price's Paraffin Engine.

a rotary pump operated by the vertical shaft at front of engine. Emergency "sight-feed" lubricators are also fitted.

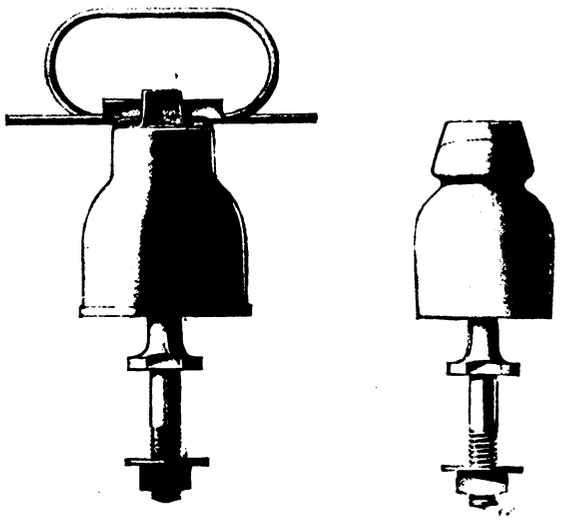
Cooling water is supplied by a gear pattern pump, and the system is arranged to clear itself through one cock in frosty weather. The governor is adjustable, and is specially sensitive to meet the narrow speed variation necessary on this class of work. Special arrangements have been made at the flywheel end of the crank shaft to avoid any wastage of oil, and the consequent throwing out of the same from flywheel rim. All bearings have been arranged to avoid oil leakage, and the plant is exceptionally cleanly in working. A large inspection door is fitted to the crank case, through which the connecting rod big end and also crank-shaft bearings can be adjusted for wear when necessary.

The generator has a capacity of 9·9 kw., and supplies current at a pressure of 100 to 156 volts. The plant is, therefore, adapted for accumulator charging or lighting direct. A noteworthy point about the dynamo is the separate commutator end bearing, which leaves the brushes fully accessible. The plant is exceptionally steady in running and almost noiseless, making it suitable for installing in the basement of a building where an outside power house is not available. Using fuel at 6½d. per gallon, the total cost per electrical unit is approximately 1⅞d. The net weight of the plant is 2½ tons.

Siemens Iron Telegraph Poles.

MESSRS. Siemens Bros. & Co. are well-known as pioneers in all branches of electrical work, but in spite of this it will doubtless come as a surprise to many to hear that they manufactured telegraph poles so long ago as 1863. In this year they first introduced their iron tubular poles, many of which have and are being used all over the world.

The taper form of tube has remained unaltered to the present day, but various modifications have been made in the design of the bases and in the joint for securing the wrought iron tube to the socket. Cast-iron is used for the base of the pole, as this metal is much less affected by the corrosive action of the earth than wrought iron. The advantages claimed for the Siemens pole are: great strength combined with light weight and low cost, small surface exposed to wind pressure, portability, compactness for shipping purposes, neat appearance, facility in erection



Figs. 1 and 2.—Standard Types of Siemens Telegraph Insulators.

and durability—a truly impressive list. Poles erected on lines over 40 years ago are, Messrs. Siemens inform us, still in use. In countries where wood is subjected to the ravages of white ants, or other boring insects, iron poles have been adopted universally.

Siemens poles have in fact been employed on the following lines: Transandine, Pacific and European, Central and South American, Indo-European, Central Persian, and on Government and other lines in South Africa, Uganda, Nigeria, Egypt, Australia, India, Argentina, Brazil, Chili, Peru, Uruguay, Mexico, China, &c.

The original type of Siemens pole consists of a tapered wrought-iron upper tube, a cast-iron base tube, a wrought-iron buckled foot-plate stamped to shape, and a lightning rod. The wrought-iron upper tube was placed in a socket formed in the top of the cast-iron base, and cement was run into the small annular space between the two. Four lugs were provided at the bottom of the base to which the buckled plate was bolted. A boss, with a conical hole in the centre, was welded into the top of the wrought-iron taper tube for the reception of the lightning rod, which consisted of a short iron rod, tapered at the end. A metal disc placed at the bottom of the socket provided a smooth surface for the wrought-iron tube to rest upon and to receive the cement. This also assisted in the important purpose of affording a good metallic connection between

Digitized by Google

the upper tube and the base, so that the pole itself might form an efficient lightning conductor. Three small wooden wedges were supplied likewise, to centre the tube in its socket whilst the joint was being cemented. The buckled plate was dipped into boiling coal tar, and the cast-iron base and wrought-iron upper tube were dipped, whilst hot, into hot drying oil to preserve them from rust.

An important improvement in the method of securing the wrought-iron tube in its socket was designed and patented a few years ago. With this form of joint, cement is entirely dispensed with and the joint is made by means of a clamping ring. The ring is made of malleable iron or steel, is of wedge shape and is cut through on one side so that a small space is left between the two edges. On its outer surface a coarse screw thread is formed and a corresponding screw thread is cast inside the top of the socket of the base tube. When the pole is being erected, the ring is placed over the lower end of the wrought-iron tube and pushed up for some little distance; the tube is then placed in the socket and the ring screwed down with a special spanner provided for the purpose, when, owing to its wedge shape, it closes tightly on the tube and is held securely in the socket. The lower end of the socket is so shaped that the bottom of the wrought-iron tube is wedged into it. This joint can be made very quickly and easily, and the only tool or appliance that is necessary is the screw ring spanner.

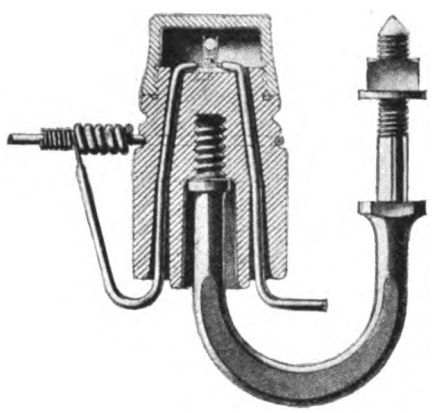


Fig. 3.—Insulator for Outside Work.

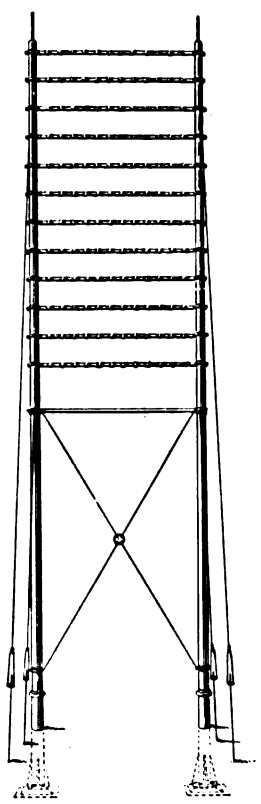

Fig. 4.—Typical Iron Pole Structure.

Another form of joint, known as the "Conical joint" or the "1872 joint," is so constructed that the wrought-iron tube fits directly into the socket of the base tube. For this purpose the socket is slightly tapered and a corresponding taper is formed on the lower end of the wrought-iron tube, so that they fit well together and make a perfectly rigid joint. This is a very convenient joint for the smaller sizes of poles.

Another modification consisted in the formation of a round flange with strengthening ribs on the bottom of the cast-iron base tube, so that the base tube might be used alone or might have a buckled plate attached if necessary. The type was introduced to meet cases where, on the same line, both very stiff and very soft soil would be found, and where it would be convenient to use the same type of pole throughout. In the one case it is obviously desirable to dig, or drill, as small a hole as possible, and, as a small base would be amply sufficient to support the pole, the flanged base tube could be used without a buckled plate, whilst in the other case, where there would be no difficulty in excavation, a large base would be necessary, and could be provided by the addition of the buckled plate.

In another type of pole the same feature as regards the bottom flange on the base tube as in the last type is retained and, in addition, the depth of the socket for the reception of the wrought-iron tube extends to the bottom of the base. The joint is always made with the screw-ring. This form affords, it is claimed, great strength to the lower part of the pole, as the wrought-iron tube so reinforces the cast-iron base that it cannot break. This type is, therefore, particularly recommended for high poles and for telephone poles which are to carry a large number of wires, especially when erected in towns, as, if the pole be overloaded or subjected to any exceptional strain, it would, at the worst, only be badly bent, whereas, with a pole in which the wrought-iron upper tube was supported above the ground level in a cast-iron base, the base might possibly break.

The pile pole consists of a cast-iron base pile which is driven into the ground by means of a rammer. The pile is in the form of a hollow tube with a solid point, and, in the act of driving, the rammer is placed in the tube, and the blows fall on the top of the solid point a wooden disc being provided to deaden the impact between the two metals. This form of base possesses several considerable advantages, viz.: the line can be erected with considerable rapidity, as two men can drive about 40 piles per day in ordinary soil. In driving, the soil is consolidated around the pile, and the upper portion of the pole can be fixed and the wires run immediately, there being no necessity to wait until the earth has settled, as in the case of poles inserted into a hole which has been dug for them, and the loose earth rammed down afterwards. No digging tools are required, the only tool necessary being the rammer. These piles are specially useful in rocky ground, as although they cannot, of course, be driven into rock, a small hole of suitable size can be formed by means of a special rock chisel or jumper, and the pile secured therein, whilst in the case of a pole with a large base, a considerable quantity of rock would have to be excavated. For ordinary telegraph lines, to carry several wires, the poles are usually constructed with a cast-iron intermediate tube bolted to the pile by four bolts, and provided with a socket to hold the wrought-iron upper tube.

The wrought-iron tube may be secured in the socket by the cemented joint, the malleable iron screw-ring joint, or, in the small sizes, by the conical joint. For light lines, to carry, say, one or two telegraph or four telephone wires, Messrs. Siemens have supplied very large numbers of pile poles which weigh about 110 lb. This pole has no cast-iron intermediate tube, the socket for the reception of the wrought-iron tube being in the pile itself. The wrought iron tube may be secured in the socket by the malleable iron screw-ring or the conical joint. This light pole has been used very largely for constructing lines in recently explored parts of Africa, as its two parts of about equal weight are just adapted for transport by native carriers. Larger poles are also supplied with the wrought-iron tube fixed directly in the pile, as described above.

In connection with the pile pole, Messrs. Siemens have lately introduced the patent steady plate which consists of a hollow boss with wings projecting from its periphery. The pile is placed in the centre of the boss and is driven into the ground until a circumferential ring, cast on the pile, comes in contact with the top surface of the plate, when, the driving being continued, the plate is forced into the ground with the pile, until its upper surface is an inch or so below the ground level. In this position the plate, being of comparatively

Digitized by Google

large surface, affords considerable additional stability to the pole when the ground is of a soft nature. In hard ground the steady plate is not necessary.

In a slightly modified form these patent plates have been supplied in considerable quantities for a district where the soil is of sun-baked bog, comparatively hard on the surface, but very soft below. A deep, tapered wrought-iron plate with two wings, called a " bog " plate, fits over the lower part of the pile and is driven into the ground with it, the position of the wings being in the direction of the line, and a second plate, called a " ground " plate, which is placed on the pile above the bog plate is also driven down until its upper surface is level with the surface of the ground, or a few inches of the soil may be removed and the ground plate buried a little below the surface. The bog plate and ground plate may also be used separately.

Fig. 4 shows a typical iron pole structure designed to carry 72 pairs of telephone wires, the height from the ground to the lowest wire being 19 ft. The structure is composed of wrought-iron poles built in sections and fixed to cast-iron bases. The bracket for the insulators are made of two channel irons, bolted back to back, and the insulators themselves are spaced 8 in. apart. Figs. 1, 2 and 3 show types of insulators which are used in connection with these poles, that shown in Fig. 3 is intended for outside stations and is designed to protect a portion of the insulated leading-in wire from moisture and consequent surface leakage. In this form the live wire is bound to the body of the insulator, the removable part consisting of a porcelain cap being screwed on to the body, and the joint being made by an indiarubber band.

New G.E.C. Controller.

THE controller shown in the accompanying illustration has been designed and is now manufactured at the Witton Works of the General Electric Co. The aim of the designer has been to produce an article thoroughly sound mechanically as well as electrically, with all parts

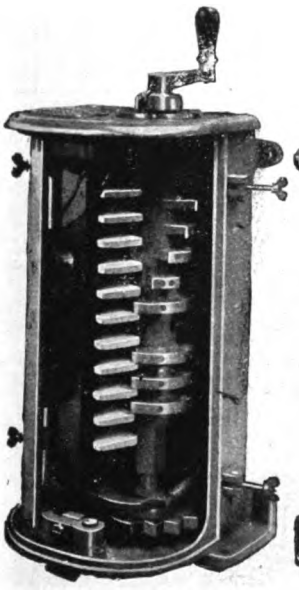

Fig. 1.—G.E.C. Controller with Cover removed.

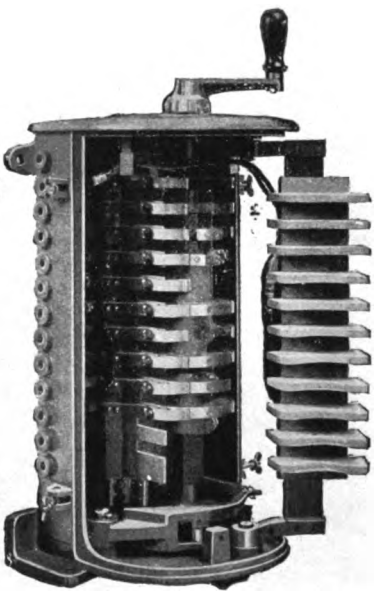

Fig. 2.—The same Controller with Blow-out Coil and Sparking Divisions swung out.

accessible, and which can at the same time be easily dismantled and reassembled.

The first illustration shows the controller in the working position with only the cover removed. Attention may be called to the large blow-out coil, the extra heavy uralite sparking divisions and the strong panel and cam wheel. Fig. 2 shows the controller with the blow-out coil and sparking divisions swung out. These swing quite clear from the controller and leave absolutely every part and every screw easily accessible for either inspection or repair. This illustration also shows the special ebonite clamps, which are provided to hold the blow-out coil leads in position. These, it may be mentioned, are in many controllers left unsupported, forming a constant source of trouble. Attention is also drawn to the ease with which the controller can be wired up. The terminals are directly opposite the cable entry holes, and are provided with sweaters of the same external diameter as the cable. Fig. 3 shows the component parts of the dismantled controller.

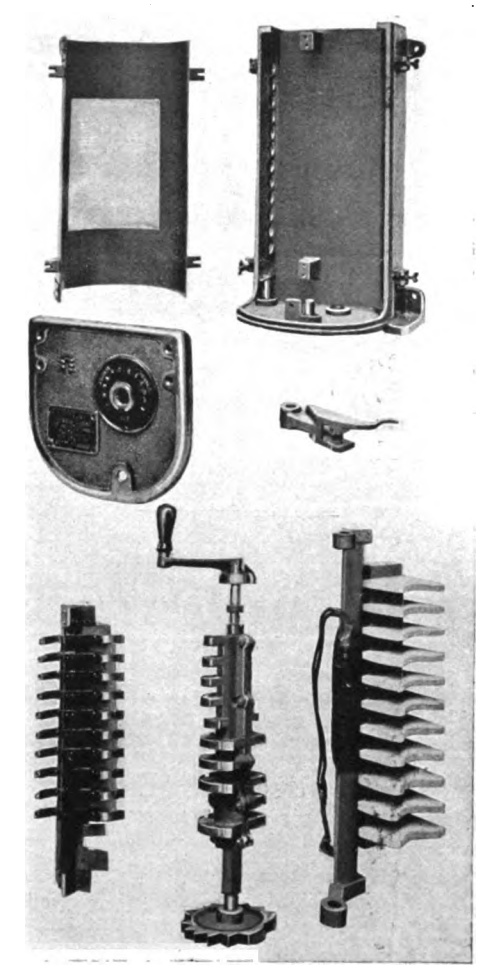

Fig. 3.—Component Parts of the G.E.C. Controller.

The case is made of cast iron and is machined where necessary. It is provided with a sheet-iron cover, held on with the usual fly nut fastening. On the back of the carcass, near top and bottom, two projections with V-shaped machined slots will be noticed. These carry the finger system, which consists of a square mild steel bar, fitting into the V-shaped slots of the above-mentioned projections, and is fixed to same with two screws at each end. This bar is micanised all over except at the extreme ends, and the finger carriers, which are wrought-iron stampings, are clamped to the micanised part. They carry on their upper end the contact fingers and on the lower cable terminals. The spark shield between the finger bar and drum is also attached to the finger bar by means of small angle pieces, which clamp under the fixing screws at both ends. Each

Digitized by Google

finger can be removed separately without taking the finger bar out of the controller.

The drum consists of four castings clamped to a micanised square mild-steel shaft, not less than two sets of screws secured with lock nuts being used on each pair of castings. The castings have projections which are turned true when in place on the shaft. The interchangeable copper contact segments are screwed to these projections.

The two ends of the square shaft are turned round. To the lower end the cam wheel is keyed. This is very strong, as is also the panel, which can be seen above the cover in the illustration. It is most important that an ample factor of safety be allowed in these two parts, and also in the panel spring, as the safe working of the controller, and therefore of the motor and what it drives, entirely depends on these parts. The handle, as will be seen, is cup-shaped to prevent rain water from filtering through the bearing of the shaft, should the controller be used in the open. Provision is also made to prevent the handle being taken away in any but the "off" position. The top plate is of cast iron with polished brass fittings.

The pole-piece, which carries the amply dimensioned blow-out coil, has fitted to its face, and reaching over the whole length of the drum, a heavy piece of fireproof insulating material. The sparking shields of uralite are cemented into slots in this piece, no screws being employed, and therefore a breakdown to earth due to the splitting of one of the uralite pieces is made practically impossible.

The controller is suitable for motors up to a capacity of 50 B.H.P. on 500-volt circuits, or for a maximum current of 75 amperes on lower voltages. It can be supplied with the leading-in holes for the cables arranged either on the left or the right-hand side.

A Formosan Power Scheme.

AS is well known, great developments have recently taken place as regards hydro-electrical installations in Japan, and it will, therefore, be of interest to describe a scheme which has been carried out by the Allgemeine Elektricitäts Gesellschaft at Ronokei, in the neighbouring island of Formosa. This station is used for supplying power to sugar factories as well as the other electrical requirements of the town of Takao. The island of Formosa, which lies just off the south of Japan, contains a number of sugar plantations, which are, however, to be found principally towards the middle and south of the island. This industry has been established a very long time, but the methods used have been very primitive, and the production has, therefore, been small. Lately, however, more modern ideas have been introduced, and sugar is now the principal production of Formosa.

Tainan is a town of 60,000 inhabitants in the south of Formosa, from which the power plant is a distance of about 25 miles. The water used for driving the turbines is collected in a large catchment area, and is brought down to the station through four large and two small pipe lines, as shown in Fig. 1. Fig. 2 shows the interior of the station, where at the present time there are four main generating sets and two exciting sets at work. In a bay opening off the generator room are placed the transformers, switchboards and high-tension apparatus. Each main three-phase generator has a power factor of 0·8, an output of 400 kw. and a frequency of 60 when running at 600 revs. a minute. The overload capacity is 25 per cent. for two hours, and the temperature rise, after working on full load for eight hours, does not exceed 40°C.

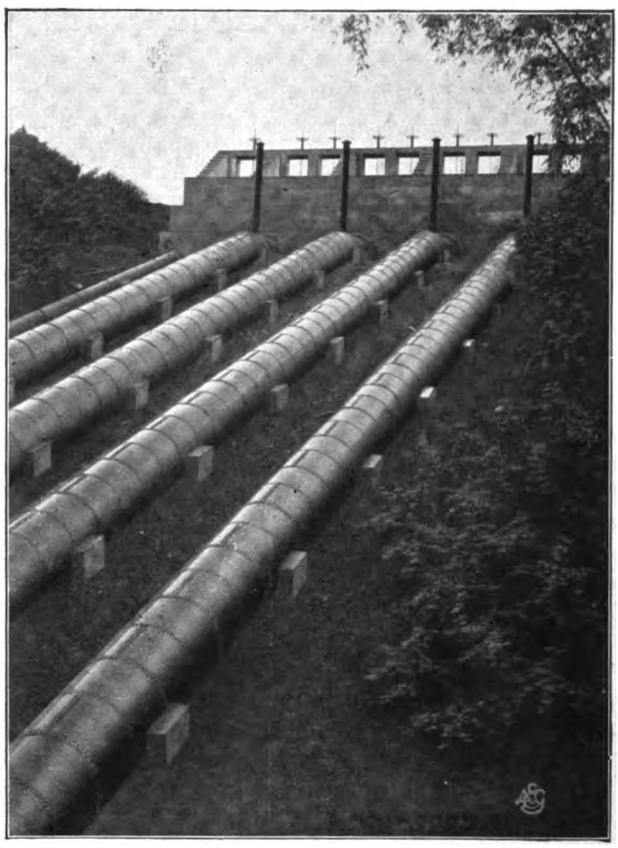

Fig. 1.—General View of the Ronokei Pipe Line.

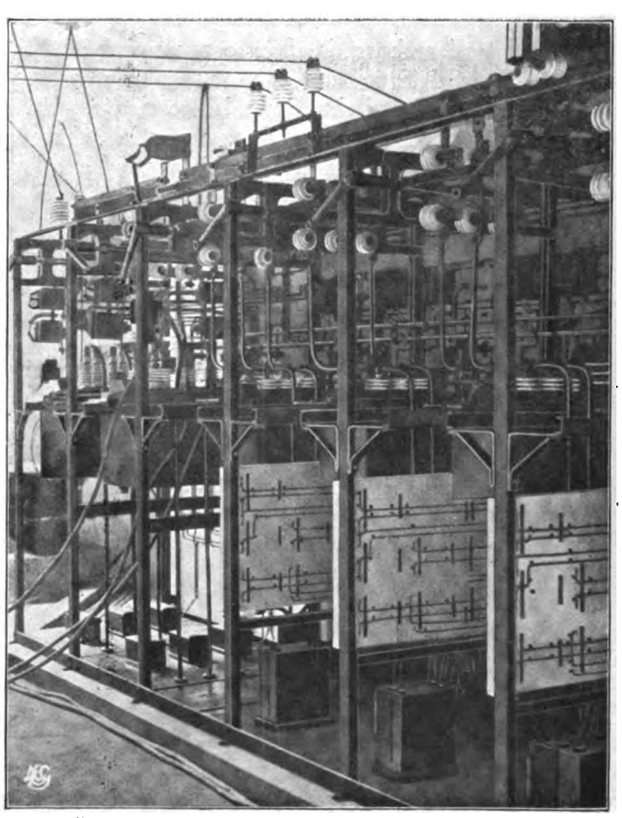

Fig. 2.—View of the Back of the Switchboard.

The generators are connected to the turbines, which are of the Francis type, by means of elastic couplings. The turbines are fitted with pressure regulators which work by

oil, and each has an output of 600 H.P. when the fall is 70 ft. Their speed is 600 revs. per min., and their efficiency 80 per cent. when running with the throttle three-quarters opened. Each exciting set consists of a compound-wound continuous-current generator direct coupled to a Francis turbine, and delivering current at a constant voltage. Each continuous-current generator has an output of 50 kw. at 125 volts when running at 750 revs. per min. The overload capacity and temperature rise are the same as those given above for the main generators. The energy from the main generators has its pressure stepped-up to 3,300 volts for transmission. Six single continuous oil-cooled transformers, arranged in two groups, are used for this purpose, while two transformers of the same size are kept as reserves. On the low-tension side the group of transformers is connected up in mesh, while on the high-tension side the connection is in star form. The overload capacity of these sets is 35 per cent. for two hours. Each transformer is designed for over 22,000 volts, and is operated from above. The transformers are built up in cells, from which they can be drawn out for overhauling and repair. The general arrangement and construction of the switchgear is shown in Fig. 2. The switchboard consists of four generator panels,

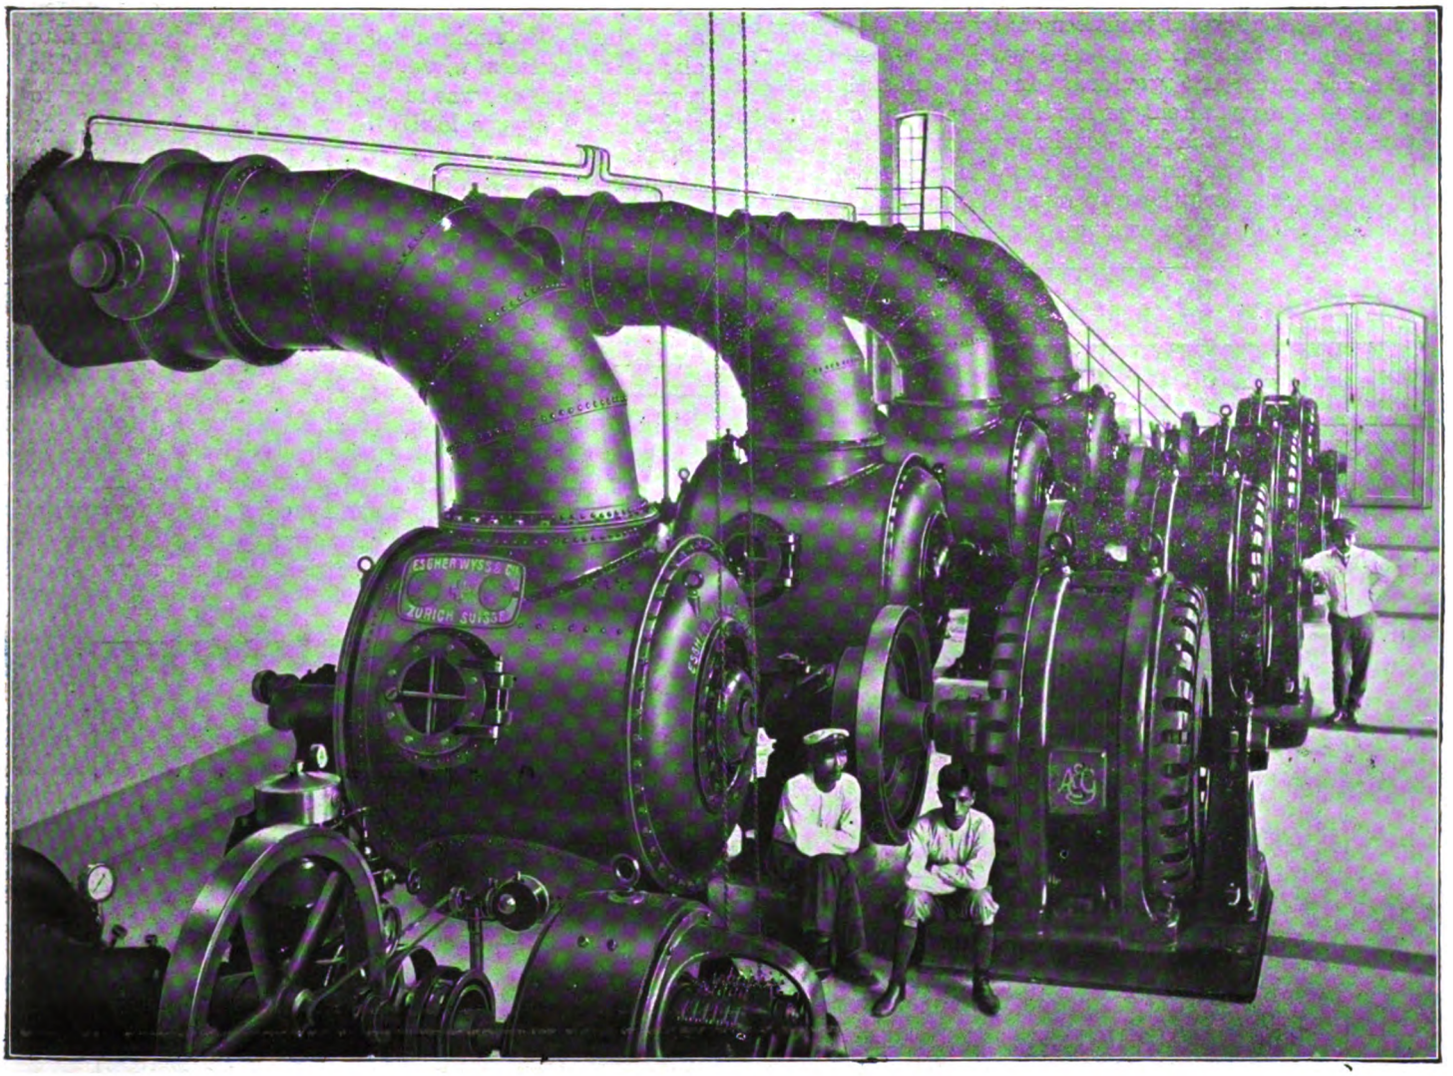

Fig. 3.—View of the Turbine Room at the Ronokei Station.

an exciting panel for the two exciting sets and two transformer panels. The overhead transmission lines consist of three stranded copper wires 0·03 mm. in area, which are fixed on wooden masts. High-tension insulators of the Delta form are being used.

At Nashiko there is a distributing station, and the overhead wire is here branched off into two lines, one of which supplies Tainan and the other Takao. Starting switches and lightning protectors are installed in this station. Each

of the two sub-stations is equipped with four 250 kw. single-phase oil-cooled transformers by means of which the high-tension voltage is stepped-down 2,400 volts. Reserve transformers are also provided. In these sub-stations there is the necessary switchgear for the distributing circuits, as well as lightning and high-tension protectors. This installation is of interest, as it shows how the modern inhabitant of Japan recognises the way in which modern engineering can be applied to the development of his country.

Battery Plant at Messrs. Rowntree & Co.'s Works.

THE services of accumulator plant for the purpose of voltage regulation and economy in working have received much recognition, and among the latest examples of this class of work may be noted a large battery and automatic reversible booster at Messrs. Rowntree & Co.'s cocoa works at York. Messrs. Rowntree & Co.'s works contain two separate generating stations, the original steam-driven plant (having an output of 2,450 amperes at 230 volts) being supplemented by a gas-driven plant situated in another part of the works, 110 yards distant, with an output of 1,600 amperes. The two stations have separate sets of 'bus-bars connected by a 2·8 sq. in. cable. The gas station usually supplies about 1,200 amperes to the steam side, but occasionally the steam supplies current to the gas station board.

Amongst the reasons in favour of the installation of a battery, the following were perhaps some of the more important:—Much importance was attached to a steady line voltage. It was thought advisable to prevent the sudden stoppage, from any cause, of any generating set interfering with the supply of current.

These requirements could only be met by the installation of a battery and automatic reversible booster. The battery was designed to supply all the peaks of the load above the predetermined outputs of the machines, and to absorb the excess when the demand falls below. The second requirement was met by arranging for the battery to assist in taking the load of any set in the event of one stopping until another be started up. The regulation of the booster is affected by balanced coils, one coil (A) being energised by a fixed percentage of the total output of the station, the other coil (B) being a shunt across the main 'bus-bars and acting in opposition to A. Thus an increase in the demand on the station tends to strengthen A, and the battery discharges. Any falling off in the demand tends to weaken A, which is then overpowered by B, and the battery charges.

The battery consists of 112 D.P. cells capable of a discharge of 800 amperes for one hour, with a final pressure of 193 volts. The positive plates are of the "Planté" pattern, $\frac{1}{2}$ in. thick, being solidly constructed to sustain heavy rates of charge and discharge without buckling or disintegration of the active material. The negative plates

Electrical Progress.

IN this article we propose to call special attention to the progress which has been made during each preceding month by electrical manufacturers in their own special lines. This progress can best be gauged by reference to selections from their latest catalogues and price sheets, and we shall, therefore, give short notes on the subject matter of such catalogues and lists as are sent us, and which indicate either that new equipment has been designed or that modifications have been made in well-known apparatus.

Power Plant.

Motor Starters.—Mr. Geo. Ellison has recently issued a pamphlet giving full details of the starters made by him for alternating-current work. Their design has been very carefully worked out, and, thinking the subject may be of general interest, we give a detailed account of this apparatus on p. 70 of our present issue.

Accumulators in Power Working.—The application of accumulator batteries to power work is certainly a feature of modern electrical engineering. The batteries have been so strengthened as to render them capable of withstanding fairly large fluctuations in demand during discharge, and they are therefore being widely used for levelling up peaks, thereby saving a certain outlay on generating plant. One of the latest of these installations has been carried out by the D.P. Battery Co. at Messrs. Rowntree & Co.'s works at York. This is described in detail on p. 90 of this issue.

B.T.-H. Motors.—The British Thomson-Houston have just designed a new type of continuous-current motor, which is capable of working in all sorts of awkward positions. To make this possible a number of different types have been made, both open, semi and wholly enclosed and dust and flame-proof. These motors can be wound for all pressures and are manufactured in a variety of sizes.

Instruments.

Elliott Instruments.—The catholicity of Messrs. Elliott's work is well indicated in some pamphlets recently issued by them. They deal with instruments of all kinds both electrical and mechanical, as well as with portable transformers, keys and switches.

Siemens' Instruments.—Messrs. Siemens Bros. & Co.'s latest catalogue on this subject deals with precision type wattmeters and current and pressure transformers. A glance through it shows that Messrs. Siemens are still keeping up that high standard which they long ago set themselves.

Reliability of Installations

can only be obtained by the use of the best System of Wiring, and experience has proved this to be **"KALKOS,"** which is now regarded as the standard of good engineering practice.

"KALKOS"

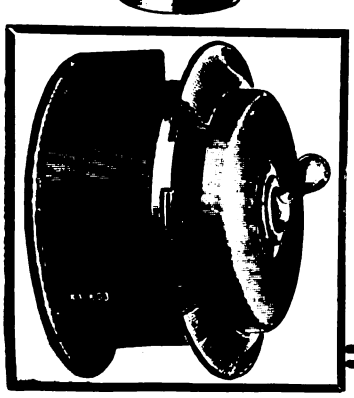
(TINNED BRASS TUBE)

Is the only system equally suitable for

Surface, Flush, or Semi-Flush Installations and Twin, Concentric or Three Wire Systems

Here are a few advantages to be obtained by using the "KALKOS" System:

- ¶ No condensation.
- ¶ It carries a substantial guarantee.
- ¶ It is easy to erect.
- ¶ One box only for Switch, Ceiling Rose, Wall Socket, &c., &c.
- ¶ Positive metallic continuity of very low resistance, affording a perfect earth.



K 95.
Designed to meet the L.C.C. requirements for hotels, licensed premises, &c. Effectively locks the cover (flush, semi-flush or surface) and prevents interference with fittings.

K 206.
With flange ring for use in semi-flush work. Cover is screwed all through.

NOTES.

Trackless Trolley Systems.

ALTHOUGH the trackless trolley system is not making any very great headway in this country, it seems to be quite an acknowledged thing for municipalities to send deputations to the Continent to investigate what is there being done in this direction. Doubtless such an investigation provides agreeable relaxation, but we doubt if there is very much more to learn than has been disclosed on previous occasions. The principle, however, that every municipality should be independent is evidently one that will continue to be followed. The latest deputation is from Bradford, and the report of the tour has now been issued. Vienna, Milan, Mülhausen and other towns were visited, but the trackless trolley was only investigated at the towns just mentioned. The system at Mülhausen is well known, and has often been cited as providing satisfactory proof that the trackless trolley is of commercial value. At Vienna the Mercedes-Stoll system is in use, and it is interesting to learn that the cost per omnibus-mile is only 4·52d. There is, however, no conductor on these vehicles, the entrance being at the forward end, so as to enable the driver to attend to tickets as well as to drive the vehicle; and there are seats for only 12 to 15 persons. The overhead construction costs £700 to £800 per mile. These figures sound encouraging, but it does not necessarily follow that the same results would be obtained in this country, because our ideals are apt to be higher. The deputation formed the opinion that 20-passenger cars at Bradford would cost about the same in running as 60-passenger tramcars, or 7·25d. per car-mile. The "Filovia" system seems to be working under particularly favourable conditions in Italy, for the service is so far appreciated that the Government is making a grant of £60 per annum per mile of route where this system is in use and where the district is not served by other means of transport. Perhaps the chief difficulty in this country is that we are not so easily satisfied as our neighbours.

Reflection in Illumination.

THERE is probably no subject in which the laws are more simple than in illumination, and equally no subject in which the laws are so frequently forgotten. The effect of reflection in illumination is a case in point. In purely scientific work it has long been realised that, for example, the loss by enclosing a source of light in a glass globe is not given simply by the coefficient of absorption of the glass. Since light is reflected as well as absorbed by the glass, the result is to increase the internal illumination of the glass, and thus the net diminution by the globe is less than might be expected from the coefficient of absorption of the glass. A similar problem was considered by Dr. W. E. SUMPNER in a Paper read before the Illuminating Engineering Society last April in regard to the Ulbricht globe for photometry. It was pointed out that if the reflecting power of the globe's surface is, say, 90 per cent., the brightness is about ten times what it would have been if merely due to the source of light. This means that 90 per cent. of the illumination in such a case is independent of the position of the source of light. As pointed out by Mr. MCALLISTER in an article of which we give an abstract elsewhere, similar principles apply to the illumination of rooms. Of course in such cases the conditions are much more complex. The reflecting power does not approach 90 per cent., or even 80 per cent., if we except a whitewashed ceiling, and thus the variations in illumination of the walls are much greater. Nevertheless the rôle of reflection in room illumination is very considerable and is sometimes brought home, even to the lay mind when the choice has fallen on a dark, though possibly artistic wall paper, and a room that was sufficiently illuminated

Digitized by Google

previously is converted into one that is comparatively dismal in appearance.

The Post Office and the Telephone.

If the business men of these isles ever give a thought to the matter, they must be looking forward with something the reverse of pleasant expectation to the state of things which will most probably exist when the National Telephone Co.'s system has been taken over by the Post Office in 1911. The present examples of Post Office administration are such as to make any other addition to that department's excursions into trading concerns absolutely undesirable. We have all had experience of them. We are not surprised, therefore, at a trenchant criticism of Post Office administration, principally in its application to the telephone system, by Mr. H. Laws Webb, in a letter published in last Wednesday's issue of "The Times Engineering Supplement." We recommend its perusal to every engineer (and even more so to the public), and are glad that it has been printed in a paper that will ensure its general recognition. Mr. Webb points out that while the engineering department of the Post Office is always on the look-out for something new and is ready to adapt new things to the work in hand, their efforts are stunted in higher quarters with the present undesirable results.

It may be pointed out that in the Post Office the engineering department has too little power, while the administration suffers greatly from the system of political control and from the subservience of the whole of the work to the fads of the Postmaster-General for the time being. It seems to us that to take the control of all the Post Office work out of the political atmosphere, by which it is at present surrounded, must be the first step towards any ultimate reformation of the whole. If a Government department is to trade it must work in a more or less business-like manner, or disaster will be the result. Further, it must be free from any pressure that can be brought to bear on it politically by its servants, and it must be administered by a man who is familiar with his work. Though at the present time each department of the Post Office is controlled by an expert chief, in practice he is often over-ruled by an inexpert politician, while the whole system of employment in Government departments leads to general inefficiency and wire-pulling. The public in general should be grateful to Mr. Laws Webb for bringing this question so forcibly to their notice. There can be no doubt that, if example be followed, telephone administration under the Post Office will become more and more inefficient. Cannot some way be found of working the system in a business-like fashion, or, at least, of keeping it free from the red-tape which at present seems the necessary concomitant of every Government operation? We are afraid not, and, unless the public take the matter in hand very quickly, another going concern will be gone beyond recall.

The Association of Consulting Engineers.

We are glad to see that the decision to form an Association of Consulting Engineers has met with general approval, though, as is only natural, there has been a certain amount of criticism, not always to the point. Thus the "Manchester Guardian" states that most of those present at the meeting were agreed upon corporate membership of the Institution of Civil Engineers being a necessary preliminary to membership in the new Association, and our contemporary goes on to say that this is not a very desirable course, particularly as the Institution is somewhat out of sympathy with the younger generation of engineers and particularly with those of the Manchester district, rather to the disadvantage of those same engineers we should think. We may say without fear of contradiction that this particular point was not discussed at the meeting in question, so that no opinion on the subject was expressed. The draft rules that had been prepared by the provisional committee were not put forward for discussion, but were left over for much more detailed consideration than would have been possible at a preliminary general meeting. It is also rather curious to notice the opinion that is held in some quarters as to the meaning of the term "civil engineer." It has certainly come to have a restricted meaning, but surely it is understood that the Institution of Civil Engineers is an institution of engineers who are not in the military service. Consequently, the Institution embraces all classes of engineer, and it is quite erroneous to suppose that the electrical, the mechanical, or gas engineer is merely received on sufferance into the membership of the Institution of Civil Engineers and is not a civil engineer. As to the particular rule in question, we think there is much to be said in its favour, because it ensures a breadth of training, but we are equally of the opinion that the council of the new Association will find it necessary to have full power to put such a rule on one side whenever it is deemed desirable.

The Late Harry W. Cox.—We have received a donation of £1. 1s. from "Dare Quam Accipere," which we propose to hand over to the fund which has been created by Alderman W. Treloar, on behalf of Mrs. Cox and her children. We invite those of our readers who are disposed to contribute to this deserving memorial to a brave man to forward their contributions to Alderman W. Treloar at 68-70, Ludgate-hill, London, E.C., or we will ourselves receive subscriptions to be handed over to Sir William Treloar.

The Electrolytic Disinfecting Plant at Poplar.—The demand for the electrolytically made disinfecting fluid whose manufacture has often been referred to in these columns seems, judging from the report of the medical officer of health, Dr. F. W. Alexander, to have been greater than ever in Poplar during the past 12 months. The year's output from seven depôts was 27,216 gallons, the maximum taken in any one month being 4,326 gallons in August and the minimum 658 gallons in December. The cost of material used in manufacturing this amount was as follows:—

Electricity, 4,781 units at 1½d. per unit	£29	17	7½
Chloride of magnesium, 2 tons 18 cwt. 11 lb.	11	16	1
Salt, 4½ tons	7	5	0
Caustic soda	3	2	6
Water	1	1	0
Total	£53	2	2½

Since the plant has been installed (a period of about four years), nearly 90,000 gallons have been manufactured at a cost for electricity and materials of under £175.

Cable Interruptions.	Date of Interruption.

Clearing House for Goods in London.—We regret to find that an error was made in our last issue in stating the cost of the clearing house scheme for London. This should have been £6,000,000, which would be sufficient to provide 2 miles of tunnels as well as the building and other parts of the complete scheme.

Searchlights in the Panama Canal Zone.—According to the "Electrical Review and Western Electrician," barges filled with stone and sand are now unloaded at the Gatun Docks by means of searchlights. There are one single and two duplex cableways for unloading sand and rock, and one searchlight for each cable has been placed on the tail towers, casting a light along the cables, on the barges at the dock and over the storage piles. The searchlights are 18 in. standard Navy projectors, and are operated by a motor-generator which converts current supplied at 600 volts from the power plant to current at 125 volts for the lamps. The lights are controlled from the head or operating towers. In addition to the searchlights, strings of flame arc lamps have been stretched from the head towers to the tail towers, four lamps for each tower. These lamps form their arc at the apex of an acute angle made by the carbons, and therefore throw a light equally in all directions. On this account, although they are strung below the level of the cables, they illuminate them as well as the storage piles beneath.

Wireless Telegraphy in German Fisheries.—The United States Consul at Hennburg, states that three Cuxhaven steam trawlers are now equipped with wireless telegraph apparatus, and that the service is so satisfactory that efforts are being made to increase it. The most marked advantages resulting from the use of the wireless telegraph in this business are the ability of captains to communicate with each other at sea as to their respective catches, and the transmission of similar reports to Cuxhaven a number of hours before the return of the ships to port. Thus vessels of the same fleet which have found poor fishing are sometimes able to join other vessels more fortunately located, in time to return with good catches. All the vessels are then able to inform the managers of the public markets respecting the quantities of fish to be placed on sale, in such manner that, in the event of unusual catches, arrangements can be made in advance for distributing supplies in the least possible time. The receipt and transmission of hydrographic intelligence and reporting of breakdowns in engines or other accidents of navigation are also features of importance.

Electricity in Mining.—The 1909 report of Mr. J. B. Atkinson (H.M. Inspector of Mines for Newcastle District) states that the total quantity of coal cut by electric coal cutters in the district (which comprises Cumberland, North Durham and Northumberland) was 468,067 tons and by compressed air 767,114 tons; the electric coal cutters in use were 45, and compressed air 178. Of the 83 fatal accidents (compared with 100 in previous year) none are attributed to electricity; of 382 separate non-fatal accidents reported to the inspector (compared with 430) four are described as electric and of 15,643 non-fatal accidents disabling for more than seven days (against 13,398) only two are ascribed to electricity. The total estimated number of shots fired was 8,664,979 and the quantity of explosives was 4,681,137 lb. The shots fired by electricity were 2,294,372, the remainder being by fuzes and squibs. No electric lamps were in use. The lamps in use were 56,892, of which 38,091 burned colza, or colza and petroleum, the remainder using petroleum, volatile spirit and "other illuminants." There were no prosecutions against mine owners. In 16,972 lamps the method of locking was magnetic and in the remainder lead rivets, screws or other means.

Obituary.—GEORGE FLETT.—We regret to have to record the death of Mr. George Flett, which occurred as the result of a motor car accident at Birmingham on Wednesday last. The deceased, with two other directors of the Metropolitan Amalgamated Railway Carriage & Wagon Co., was proceeding from the works to the New-street station when a child ran into the roadway close to the car. The driver, in swerving out of the way, ran into the curb, with the result that the car was overturned. Mr. Flett, who was next the driver, received fatal internal injuries, while the other occupants were badly shaken and the child will probably not recover. Mr. Flett's position in the electrical engineering profession is well known to our readers. He was managing director of Messrs. Dick, Kerr & Co., and has done much in assisting the progress of manufacturing electrical work. As the announcement of Mr. Flett's death has come to hand at the moment of going to press, we are now only able to refer to his work in this brief manner. We hope, however, to place on record our appreciation of Mr. Flett's activities in our next issue.

Luminous Efficiency of the Firefly.—In a recent issue of the "Bulletin of the Bureau of Standards," Messrs. H. E. Ives and W. W. Coblentz describe an investigation of the light emitted by the common firefly. The spectrophotometric curve of the firefly, as compared with a carbon glow lamp, was obtained by comparison of the photographic densities of the negatives from the firefly and the glow lamp. From the known distribution of radiant energy in the carbon glow lamp, and by means of the spectrophotemetric relationship, the distribution of radiant energy of the firefly was derived. The light was found to consist of an unsymmetrical structureless band in the yellow green of the spectrum, with a maximum at 0·57μ, and extending to 0·51μ and 0·67μ. The luminous efficiency of the firefly is calculated by the authors as 96·5 per cent., as compared with 0·4 per cent. for the carbon glow lamp, and about 4 per cent. for the most efficient artificial illuminant. This value is obtained on the assumption that there is no infra-red radiation, other than that due to the natural body heat. They state that there are reasons for believing that the light emitted is due to a physiological-chemical reaction, not necessarily accompanied by heat waves of low frequency such as occur in a purely thermal (low temperature) radiation. But even if heat waves of low frequency are generated in the photogenic cells, they could not pass out into space on account of the opacity of the outer integument, the chitinous layer, of the insect, which probably can transmit radiation to wave lengths as great as 1·5μ. Now, from present knowledge of emission and absorption, and from the fact that the emission band in the visible spectrum stops abruptly at 0·7μ, it appears highly improbable that there is appreciable radiation between 0·7 and 1·5μ; hence the assumption of no infra-red radiation cannot seriously affect the results.

Science at the Japan-British Exhibition.—An interesting display of scientific apparatus, maps, specimens and statistics are to be found in that part of the Japan-British Exhibition which lies between the Shepherd's Bush and Wood-lane entrances. Oceanography, astronomy, anthropology, metrology, physics, geography, chemistry, geology and mathematics are all represented, and an inspection of the various exhibits will not be without its educational value to those visitors who can tear themselves away from the joys of the "Witching Waves." The principal exhibitors in the electricity and magnetism section are the Wheatstone Laboratory, King's College, London, from which several historical pieces of apparatus used by Wheatstone and Clerk Maxwell are shown; the Cambridge Scientific Instrument Co., who are showing standard cells and resistances, a Callendar-Griffiths bridge, oil bath oscillograph and twisted strip ammeter; and Mr. R. W. Paul, who is showing selections of the various instruments designed by Dr. Sumpner and Mr. Campbell, including the reflecting alternate-current dynamometer, vibration galvanometer and mutual inductance standard. Dr. C. V. Drysdale has lent some instruments designed in accordance with the results of researches which have recently been published in THE ELECTRICIAN, including a double wattmeter, phase-shifting transformer and direct and alternate-current potentiometer. In this connection, Mr. R. W. Paul has lent a compensated standard resistance coil and a universal standardising bridge, and Messrs. Nalder Bros. & Co. a plug permeameter. Mr. B. S. Cohen is also

Digitized by Google

showing specimens of the apparatus which he has designed for telephone work.

Telephones on Trains—It is stated that the London, Brighton & South Coast Railway intend to fit the "Southern Belle" express with the Kramer system so that passengers can transmit telephone messages when the train is in motion. The system appears to depend essentially upon induction between a coil of wire on the train and the wires alongside the railway.

St. Marylebone Undertaking.—In our last issue we commented on the progress of this undertaking, but we fear that our note was a little ambiguous in regard to the capital charges. The 1·42d. per unit there mentioned refers only to the compensation paid to the company, or what may be termed "dead capital." The total capital charges (including special charges) reach the high figure of 2·52d.

The Maley Brake.—We have received a pamphlet from the Electro-Mechanical Brake Co., of West Bromwich, replying to a Paper read before the Institution of Electrical Engineers by Mr. A. Gerrard, describing tests which were to the disadvantage of the Maley brake as compared with the modified Westinghouse brake used at Glasgow. The pamphlet states (1) that the tests made by Mr. Gerrard were rough and not sufficiently accurate to make comparisons of any value: (2) that a brake can only be tested by accurate tests on ordinary greasy rails; (3) that the tests on the Maley brake were made unknown to, and without the experience of, the patentee, whereas the tests made on the Westinghouse brake were carried out after many months of experience; (4) that the Maley brake was tested with insufficient and improperly graduated resistance; (5) that the name of the Maley brake was suppressed, although the brake was fully illustrated; and (6) that Mr. Gerrard omitted tests made in the presence of the patentee showing better results than those obtained by Mr. Gerrard in his private tests. It is stated that the former included very satisfactory stops on a greased rail, a condition under which the tests on the Westinghouse brake were not recorded. A good deal of detailed criticism is given of Mr. Gerrard's tests, and the independent tests made at Leeds are compared with the Glasgow tests. In conclusion, many figures are given showing the total brake power, efficiency, relative amount of braking done through the wheels, relative motor output, and braking force on the rails for the two forms of brake. It is impossible to deal briefly with such data, and we would therefore advise our readers who are interested in the subject to write to the company for a copy of the pamphlet.

Current Topics.

Subjects of current interest dealt with in this issue include the following:—

Dr. C. V. Drysdale contributes an article on "The Testing of Transformer Regulation."

Mr. J. Rezelman concludes his article on the "Analysis of Reactance."

We give a description of the plant laid down by the Anglo-Newfoundland Development Co. for the manufacture of paper from wood pulp, the paper being used for the printing of the "Daily Mail" and other papers of the Amalgamated Newspaper Co. of London.

We give an abstract of the report describing the year's work at the Reichsanstalt.

A report by Messrs. Mordey & Dawbarn has been issued on the working of the Dolter surface contact system at Torquay.

A report by a deputation of the Bradford Corporation has been issued as the result of a visit to certain Continental towns in which trackless trolley systems are in use.

In the hall of the Institution of Civil Engineers to-day (Friday) there will be a meeting of the members of the Institution of Mechanical Engineers, and a series of Papers dealing exclusively with the electrification of railways will be read.

Barnstaple Council have met with a curious experience in connection with their efforts to popularise the consumption of electrical energy for various domestic purposes. It has been found impossible so far to get a firm of contractors who will take up the supply of electric fittings and wiring of premises on lines similar to those of the gas company.

In the course of an inquiry before Mr. H. Ross Hooper at Aston to obtain permission for the Corporation to borrow £23,105 for electricity purposes, the Board of Trade Inspector congratulated the Electricity Committee on the eminently satisfactory profits of the undertaking.

The great usefulness of wireless telegraphy at sea has been further exemplified in the case of the missing Dr. Crippen and Miss Le Neve, whose whereabouts appear to have been located by its means.

The service which wireless telegraphy can render in the event of such catastrophes as a ship on fire was demonstrated off the American coast, where it was the direct means of saving 205 souls.

An unusual accident occurred at a colliery at Blaydon, where a deputy foreman named Barrett met his death while attending to the telephone, due to contact between the telephone line and a main cable whose insulation had become damaged by contact with a steam pipe.

Legal.—At Birmingham a point was raised as to the operation of the Employers' Liability Act. A firm of electrical manufacturers was summoned for having left machinery unfenced. The defence was that the guard had been left off the machine by a fellow-workman of plaintiff's. It was pointed out that the defendants were not exempt on this ground unless they had secured a conviction against the delinquent workman, and an adjournment was granted.

Companies Meetings and Reports.—Many points of interest were referred to in the speech of the chairman of the National Telephone Co. at the meeting of shareholdersyesterday (Thursday).

The meeting of the stockholders of the City & South London Railway was interesting, apart from the statement of the chairman, from a proposal made by Col. Perry that the name of the company should be changed to the "North & South London Railway." The result of the past year's working shows a large increase in season tickets but a poor response to the directors' considerable reduction of fares.

A line of London railway which would probably greatly benefit from electrification is the East London Railway, which forms a very useful link between the Metropolitan and the Metropolitan District, and some other railways in the East End of London, running from Shoreditch to New Cross. Lord Claud Hamilton made an interesting statement at the meeting on Tuesday, and foreshadowed a possible arrangement with some of our large contracting electrical firms on the basis of easy payments.

Mr. F. L. Rawson, presiding at a meeting of the British North Western Synd. (Ltd.) referred to an option the syndicate had obtained for practically the whole of the water-power of the Dettifoss Falls, Iceland, equal to 720,000 H.P.

At the meeting of shareholders of the Direct United States Cable Co. the chairman stated that, so far as that company was concerned, there was no truth in the statements that have been industriously circulated as to modified arrangements or working agreements with a large telephone company in the United States. The revenue to the company shows steady improvement.

INSTITUTIONS AND SOCIETIES

Institution of Civil Engineers.—It is announced that H.M. the King has been graciously pleased to become the patron of the Institution of Civil Engineers. His Majesty, as Prince of Wales, was an honorary member for 17 years before his accession.

Royal Meteorological Society.—H.M. the King has also graciously consented to become the patron of the Royal Meteorological Society.

ARRANGEMENTS FOR THE WEEK.

INSTITUTION OF MECHANICAL ENGINEERS.

FRIDAY, July 29th (to-day).

10 a.m. Meeting at the Institution of Civil Engineers, Great George-street, London, S.W. Papers on "Electrification of Suburban Railways," by Mr. F. W. Carter; "Cost of Electrically Propelled Suburban Trains," by Mr. H. M. Hobart; "Economies of Railway Electrification," by Mr. W. B. Potter; "Electrification of Trunk Lines," by Mr. L. R. Pomeroy; and "Electrification of Railways," by Mr. G. Westinghouse.

Digitized by Google

LIVERPOOL CORPORATION TRAMWAYS.

Among the large electric tramway undertakings of this country that of the Liverpool Corporation takes a prominent position; and as this municipality terminates its financial year at an earlier date—viz., December 31st—than most other local authorities, we propose to take its tramway accounts first for analysis.

Both as regards the number of passengers and total receipts a decrease is shown for the year 1909 compared with the figures for the previous year. This decrease, although only 0·3 per cent., represents 394,943 fewer passengers and £1,873 less revenue, so that it is satisfactory to record an increase in the net profit, which latter amounted to £82,354, whilst the sum contributed in relief of the rates (£27,451) is £2,593 in excess of the sum set aside for this purpose in 1908. This result has only been possible owing to a decrease of £6,867 in the operating costs, brought about by economies in the management of the undertaking.

As showing the flourishing condition of these tramways, it may be mentioned that since the undertaking came into the possession of the Corporation £234,971 has been contributed in relief of rates and £717,851 has been set aside for the redemption of debt, whilst £228,677 has been paid in rates and taxes since 1897 and £502,713 set aside for reserve, renewal and depreciation funds.

The traffic receipts for the past year amounted to £561,271, or 11·27d. per car-mile, compared with 11·04d. in 1908, the revenue per car-mile being the highest yet recorded. The number of passengers was 121,532,940, a smaller total than in any year since 1904, whilst 11,952,373 car-miles were run (*i.e.*, fewer than in the preceding five years). The total number of units used was 22,747,990, equivalent to 1·87 units per car-mile, the energy being purchased from the electricity department at an average cost of 1·09d. per unit.

Mr. C. W. Mallins mentions in his annual report that the policy of the Committee in deciding to undertake their own insurance against third party risks has so far operated very successfully, the first 19½ months working showing a credit balance of £11,694.

We have on a previous occasion referred to the success attending the experimental first class tramway cars. In these, inside passengers only are charged higher fares, outside passengers paying the ordinary fares. We may mention, however, that the average earnings per car-mile of these first-class cars has increased from 5·26d. to 10·92d.; and a further experimental quarter-hourly service of first-class cars is to be established on the Croxteth-road route.

In regard to the division of passengers over the various stages, the large majority of passengers pay a penny fare—viz., 89·7 per cent. of the total; whilst 9·7 per cent. purchase 2d. tickets. (It may be here noted that ½d. and 1½d. fares are not in force.) As indicating the density of the tramway traffic at various points in the city, it is interesting to notice that 5,882 cars arrive at and leave the pierhead every day in the busy season, whilst at several important junctions between 3,000 and 4,000 cars cross daily. The total number of cars owned by the Corporation is 531.

The plough type of lifeguard continues to do good service at Liverpool, as may be judged from the fact that 38 persons who had been knocked down or who had fallen in front of the cars were pushed clear of the track without serious injury. There was also a decrease of 50 per cent. in the number of fatal accidents during 1909, the ratio of fatalities to the number of passengers carried being 1 in 30,383,235. Thirty-two fatal accidents were recorded in the city during the year, caused by vehicles other than tramcars.

The number of articles left on the cars amounted to 30,176, an increase of 1,930, or 6·8 per cent. over the number in the previous year; and 45·6 per cent. of the articles were unclaimed.

We give below an analysis of the cost of working for the year 1909, the cost per car-mile for the previous year being also included to facilitate comparison.

		Per car-mile. 1909.	1908.
Traffic Expenses.			
Superintendence	£4,709	0·09d.	0·10d.
Wages of motormen and conductors	101,070	2·03d.	2·00d.
Wages of other traffic employés	13,634	0·27d.	0·29d.
Cleaning and oiling cars	13,810	0·28d.	0·27d.
Cleaning, salting and sanding track	2,780	0·06d.	0·04d.
Fuel, light and water for depôts, &c.	2,166	0·04d.	0·04d.
Ticket check	6,738	0·13d.	0·13d.
Uniforms, &c.	2,871	0·06d.	0·08d.
Lighting routes and miscellaneous	3,107	0·06d.	0·04d.
Total Traffic Expenses	£150,885	3·02d.	2·99d.
General Expenses.			
Salaries	£8,323	0·17d.	—
Superannuation	414	0·01d.	—
Auditors' fees	100		
Store expenses	976	0·02d.	—
Rates and taxes	29,640	0·60d.	—
Advertising, printing and stationery	1,139	0·02d.	—
Fuel, light, cleaning offices, &c.	883	0·02d.	—
Law charges	57	—	—
Compensation (including £12,000 transferred to compensation fund account	12,193	0·24d.	—
Insurance	1,115	0·02d.	—
Miscellaneous	3,777	0·08d.	—
Total General Expenses	£58,617	1·18d.	1·13d.
Repairs and Maintenance.			
Permanent way	£29,089	0·58d.	0·59d.
Electrical equipment of line	5,677	0·12d.	0·14d.
Buildings and fixtures	1,589	0·03d.	0·04d.
Workshop tools	501	0·01d.	0·01d.
Cars	44,367	0·89d.	0·88d.
Other rolling stock and miscellaneous	371	0·01d.	—
Total Repairs and Maintenance	£81,594	1·64d.	1·66d.
Power Expenses (cost of current and contribution to fuel guarantee fund)	£103,219	2·07d.	2·09d.
Rental of leased lines	£5,891	0·12d.	0·11d.
Total Working Expenses	£400,206	8·03d.	7·98d.
Interest	£50,919	1·02d.	2·15d.
Sinking fund	59,249	1·19d.	
TOTAL EXPENSES (including capital charges)	**£510,374**	**10·15d.**	**10·13d.**
REVENUE.			
Traffic receipts	£561,271	11·27d.	11·04d.
Advertising	7,643	0·15d.	0·55d.
Miscellaneous	5,652	0·11d.	
Interest	18,162	0·36d.	
TOTAL REVENUE	**£592,728**	**11·89d.**	**11·59d.**
Surplus	£82,354	1·65d.	1·46d.
This surplus was allocated as follows:—			
Contribution in aid of general rate	£27,451	0·55d.	0·49d.
Reserve, renewal and depreciation account	54,903	1·11d.	0·97d.

The capital expenditure during the year amounted to £39,095, bringing the total expenditure to £1,969,697. The outlay during last year was mainly occasioned by extension of the permanent way, this accounting for £26,737, whilst £6,213 was spent on cars and £5,628 on land and buildings. The details of the capital expenditure, therefore, differ only to a small extent from the figures given in our analysis of the previous year's accounts (THE ELECTRICIAN, July 16, 1909).

RECENT ARRANGEMENTS FOR THE PARALLEL RUNNING OF ELECTRIC MACHINES.*

BY W. WOLF.

Summary.—In the present article this important question is discussed. The author deals with the methods employed by the leading firms on the Continent, both for the parallel running and synchronising of electric machines.

In order to run electrical machines in parallel satisfactorily special arrangements are necessary, unless they have a dropping characteristic, like shunt machines; for those units having a rising characteristic produce a greater E.M.F. with increasing current, and, therefore, gradually take over the whole of the load and drive the other

* Abstracted from the "Elektrotechnik und Maschinenbau."

Digitized by Google

machines as motors. The following article deals with some methods (which are all patented) of obviating this difficulty.

The use of steam and explosion engines for driving the generators direct presents great difficulties, due to resonance between the prime mover and the network. However, the transmission of the pulsations to the generator can be overcome by the use of elastic couplings. With machines having different speed regulation and self-induction, such as two machines driven by a turbine and a reciprocating engine, although it is possible to run them in parallel under normal conditions, yet when a short-circuit occurs, the turbo-generator may be seriously damaged before the circuit-breaker operates. This is obviated by the A.E.G. by fitting a counter-compound winding to the turbo and connecting a choking coil in parallel. Normally this compound winding takes but little current, but with a sudden overload the greater part of the current flows through it owing to the self-induction of the choking coil, and thus the field strength is diminished, and the turbo is prevented from taking its share of the overload until the circuit-breaker operates.

The arrangement of the Lahmeyerwerke is to divide the windings into the same number of parts as there are machines to be driven in parallel and to connect them in such a way that each circuit consists of one part of each of the divided windings.

Although simple shunt machines will run satisfactorily in parallel, those with series compensating windings are not stable. For this case Parsons connects two points of the compensating windings together by an equalising connection. If the E.M.F. of one machine is momentarily greater than that of the other, due to an increase in speed, a part of the armature current of the first machine flows through the connection into the compensating winding of the other machine, whereby the magnetising component of the compensating winding of the first machine is smaller than the demagnetising component of the armature reaction, and the E.M.F. of this machine is decreased. In this way the parallel running is stable. The same method can also be applied to compound machines, or they can be supplied with counter-compound windings.

Synchronous generators have a considerable voltage drop, especially on inductive loads. To compound them the excitation is usually

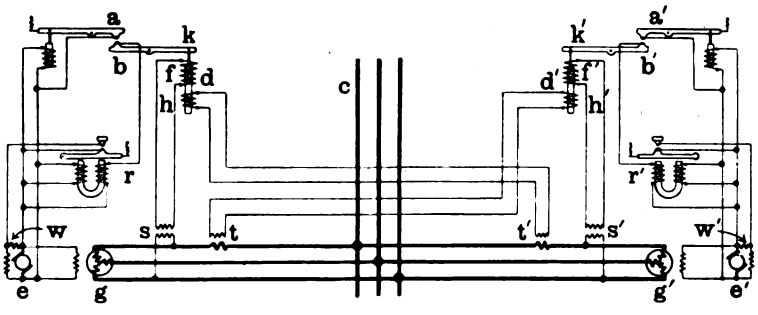

Fig. 1.

through an automatic regulator in such a way that by regulation of the excitation voltage the generator voltage remains constant for a given load and increases with increasing load. This method is desirable when the voltage of some point distant from the station is to be kept constant, and, therefore, the generator voltage must be increased with the load to compensate for the line drop.

As will be seen from the figure, this is accomplished by the use of the well-known Tirrill regulator, which is adapted for this case by exciting the series coil of the regulator for the one machine by means of the current flowing in the other. By choice of the phase in which the current transformer is placed or of the resistances or choking coils or condensers which are connected in series with the series or shunt windings, any desired distribution of watt or wattless load may be obtained.

The Siemens-Schuckertwerke use a differential method for the automatic distribution of the load, in which a relay for each machine is excited in opposite directions by some part of the total current and the current of the single generator. This method is not satisfactory, owing to the difficulty of adjusting the relays.

This trouble is overcome in the methods shown in Figs. 2 to 4. In these the relays are magnetised by single coils in which currents proportional to the out-of-balance currents flow. Of course, the relays must be so arranged that they do not only depend on the strength of the out-of-balance currents, but also on their direction with direct current or on their phase with alternating current.

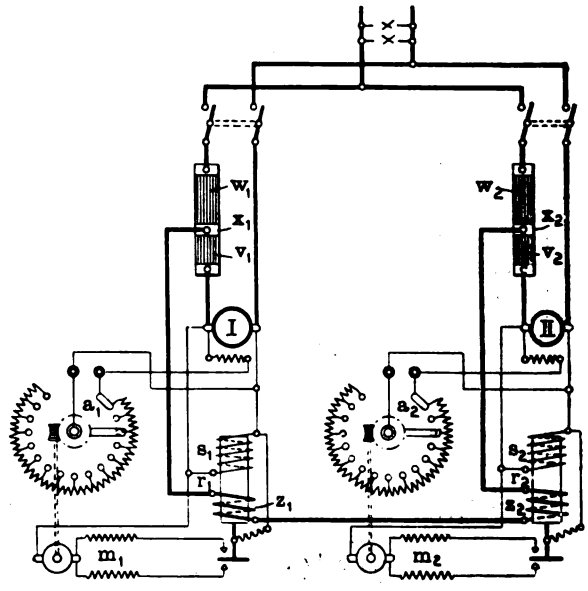

Fig. 2.

made dependent on the load. The A.E.G. effect this compounding by the use of condensers, connected either in the circuit of each generator or in the common leads. If the generator is inductively loaded the current produces a pressure drop in the machine and a rise in the condenser. By varying the capacity of the condenser or the ratio of the series transformer, this drop and rise can be made equal. Also the rise can be made greater or smaller than the drop, corresponding to over or under-compounding. The compounding will be approximately correct even if the phase of the current varies. In this way the generator and condenser work together like a direct-current compound machine. The A.E.G. turn the compounding arrangement into a counter-compound effect in order to meet the overloads in a more efficient way. The rectifier or another part of the compounding device is fed by two series transformers, of which one is connected for compounding and the other for counter-compounding. In normal running only the first is in circuit and the other cut out, while when a short-circuit occurs an automatic switch reverses these connections.

Instead of operating the switch, however, by means of the alternating current of the machine the exciting current can be used when it varies with the former, as, for example, when a rectifier is employed. The magnets of the switch have simpler construction, smaller dimensions and more accurate working when they are fed by direct current. Each generator must be controlled in the above way and the automatic switches can be either entirely independent of each other or completely or partly dependent.

In Fig. 1 is shown a device for the automatic distribution of the load on two direct-current, single or three-phase generators running in parallel and independent of each other. They are each excited

In order to make the relays work in this way a permanent excitation is provided of such a strength that these differential currents can never reverse the direction of the total excitation, so that obviously the displacements of the relay are dependent on the direction or phase of the current. Since only one current coil is used for the out-of-balance currents and the differential action is produced by fixed, not too sensitive, arrangements outside the relays, a considerable simplification in the working and maintenance of the apparatus is obtained, and the use of a large number of turns of wire is avoided, which to a large extent counteract each other.

Fig. 2 shows this method in the simplest form for only two direct-current machines. I and II are the armatures of the two generators, which are provided with automatic regulators a_1 and a_2 for the shunt excitation. The regulators are in this example variable resistance switches, and are driven in either direction by the auxiliary motors m_1, m_2, the relays r_1, r_2 serving to reverse them. A resistance is connected in the main circuit of each generator, and these are divided into the parts v_1, w_1 and v_2, w_2. The series coils z_1, z_2, which work in opposite directions on the relays r_1 and r_2, are connected to the dividing points x_1 and x_2. The permanent excitation is produced by the shunt coils s_1 and s_2.

The resistances v_1, w_1 and v_2, w_2 can be so arranged that the points x_1 and x_2 are equipotential for normal load distribution. As long as this condition holds no current flows through the coils z_1 and z_2. But if the generator I should take a larger part of the load than desired the out-of-balance current flows from x_1 to x_2, and excites the relay r_1 in the direction for lower and r_2 in the direction for higher voltage, so that the automatic regulator comes into operation, and the desired load distribution is restored.

Digitized by Google

The more general form is shown in Fig. 3, for any number of generators in parallel. In this case all the series coils are excited in the same direction. Each generator has now two resistances in parallel, which are each divided into two parts, t_1 and u_1, and v_1 and w_1, &c. The points y_1, y_2, y_3 are connected together, so that the total current is divided in a given ratio between the portions w_1, w_2, w_3, which must correspond to the normal load distribution of the generators. In this case no current flows along the connection between y_1, y_2 and y_3. The dividing points are so arranged also that normally no current flows in the coils z_1, z_2, z_3. But if generator I takes too much of the load the voltage drop in the part u_1 is greater than in the parallel parts w_1, w_2, w_3, and so a current flows from x_1 to y_1, and the relay lowers the voltage of generator I. In this method the series coils z_1, z_2, z_3 are excited in the same direction on their relays; the differential action is obtained by the difference in voltage drop in the parallel resistances of each generator.

Lastly, a device for the automatic regulation of the wattless load of two three-phase generators in parallel is shown in Fig. 4. The two generators I and II are again provided with relays r_1 and r_2, which vary their excitation. Instead of the variable resistance regulator used before a quick-acting regulator is employed, in which resistances q_1 and q_2 are periodically short-circuited by the contacts c_1 and c_2. The duration of the short-circuit is determined by the position of the relays r_1 and r_2. The relays are again provided with shunt coils s_1 and s_2 connected to one phase of the network, and these have comparatively large ohmic resistances p_1 and p_2 in series to reduce the self-induction in comparison to the total resistance. Without these relays the network voltage would produce fields in

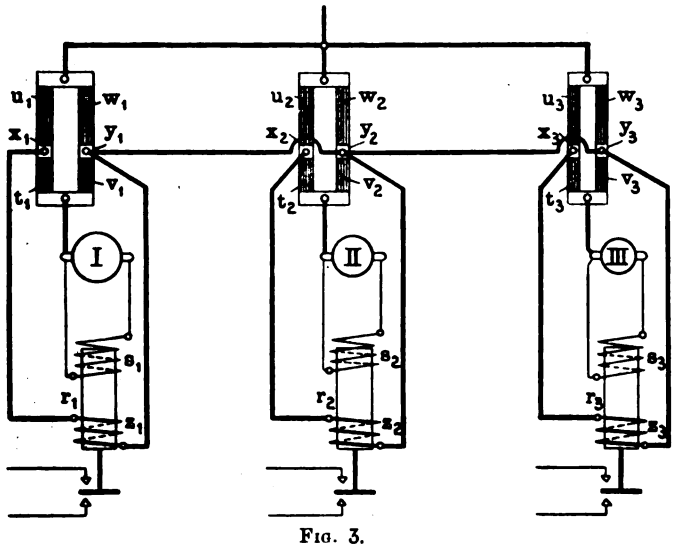

Fig. 3.

the relays, which would defeat the purpose of the latter. The series coils z_1 and z_2 are connected in opposite directions with the series transformers f_1 and f_2. These are also connected in series, so that a current always flows in them. If the two transformers are properly related to each other, for any currents flowing in their connections the tapping points are equipotential, provided that the currents are in phase. In this case the coils z_1 and z_2 connected to these tappings have no current. But this immediately alters as soon as a shifting of phase due to a wattless out-of-balance current occurs, in which case the coils z_1 and z_2 receive currents in the proper direction to make the relays produce a proportionate distribution of the wattless load.

These relations are shown more clearly in the diagram (Fig. 5), in which e_1, e_2 and e_3 denote the phase voltage, s the ampere-turns of the coils s_1 and s_2 connected between phases e_1 and e_3 (*see* Fig. 4), their inductance being neglected, i_I and i_{II} the generator currents corresponding to phase e_2. With a non-inductive load, i_I and i_{II} do not coincide with e_2 when an out-of-balance current is present, but i_I will lead and i_{II} lag, so that the vectorial difference z works the relay, z being a measure of the phase difference between i_I and i_{II}.

If the currents are alike in phase, the out-of-balance currents do not act on the relays if the vectors for the series and shunt windings are perpendicular to each other with proper distribution of the wattless current. If the currents are not only unlike in phase but also unequal, the out-of-balance current is not perpendicular to the voltage e_2 (Fig. 6). Resolving z into its horizontal and vertical components h and v and combining z with s, Fig. 7 shows the comparatively small effect of h.

The above method becomes very complicated when the various units which are to be run in parallel are situated in different stations, owing to the large number of connecting leads and to the fact that the regulation of each machine has to be dependent on the main station. The Siemens-Schuckertwerke employ a method for overcoming this difficulty, in which the series coil of the relay is fed by a series transformer in the circuit of its own machine, and the shunt coil is connected through an adjustable phase converter. In this way the regulation of each machine can be adjusted by hand according to the power factor of its own load.

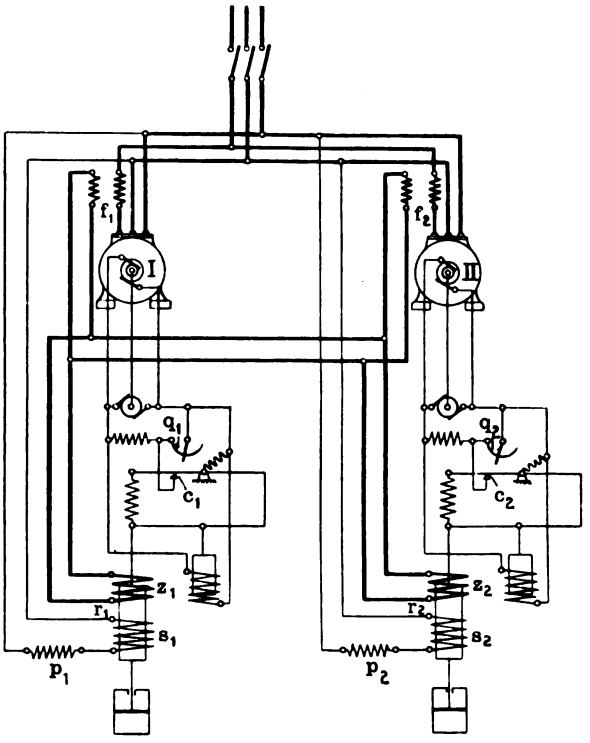

Fig. 4.

The firm of Voigt & Haeffner employ a method of synchronising three-phase generators in which three relays are used instead of the ordinary three lamps. Two of the relays are set up opposite each other with a swinging arm in between them. When one relay is excited this arm is pulled towards it, and makes a contact in a circuit, which consists of an auxiliary source of direct current and a coil which accomplishes the automatic regulation of the machine for the "too fast" condition. When the other relay is excited the arm

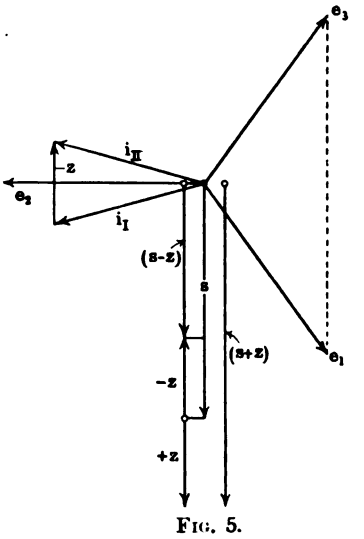

Fig. 5.

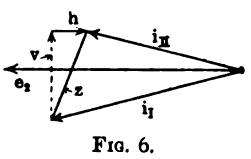

Fig. 6.

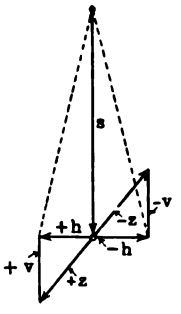

Fig. 7

moves the other way and makes contact in a similar circuit for the "too slow" condition. On the third relay being excited the circuits of both the other relays are broken simultaneously. When the arm is attracted towards the first relay it remains in that position as long as the relay is excited, even if the second relay is excited afterwards, because its distance from the second relay is greater than that from the first.

Digitized by Google

Now suppose the relays are excited in the order "first, second, third," the arm is attracted towards the first relay and makes contact for the regulation of the machine to reduce the speed. The second relay is then excited, but does not pull the arm over, and the third breaks the contact of the other two. This cycle is repeated, so that contact is made practically continuously in the regulation circuit on the "too fast" side, until the speed of the machine has been reduced to the correct value, when the cycle stops and the machine can be switched in. In the same way if the order of the relays is "second, first, third" the contact is made on the "too slow" side, and the speed of the machine is increased to the proper value. A lamp is placed in parallel with each of the regulating coils, so that the operations may be seen. When they are both dark the machine can be switched in.

THE WORK OF THE PHYSIKALISCH-TECHNISCHE REICHSANSTALT IN 1909.

The recognition of the good influence that may be exerted on a nation's affairs by the establishment of an institution, in which scientific research is carried on and to which questions requiring an expert answer by unbiased authority may be referred, was certainly a step forward on the road of progress. Four great powers have now each their own institution, but doubtless the most famous of them is the Physikalisch-Technische Reichsanstalt at Charlottenburg. Both the testing and research work carried on there are excellent and the annual report indicates the present position of physical science in no uncertain way. We, therefore, in what follows give some details of the electrical work done there during the past year, abstracting our account from the "Zeitschrift für Instrumentenkunde."

Electricity.—General.—The measurements made on electrical standards consisted partly of those periodical tests carried out in the Reichsanstalt itself and partly of tests made in conjunction with the other national physical laboratories, in accordance with the conference held in London in 1908. Also the proposal made in the spring of 1909 for the interworking of the German, English, French and American laboratories required that certain further researches and preparations should be undertaken.

Resistance Measurements.—For testing the manganin standards used in Section I. the mean value, 1·001745 ohms, determined during the last 12 years was employed. On this assumption small permanent variations of the order of one $\frac{1}{100000}$th compared with those of the year before were obtained. In order to verify again this mean value, four manganin coils were tested against the mercury standards No. XI. and XIV., which since they were last measured in March, 1905, have remained full of mercury. The value thus determined agreed with the figure given above within $\frac{1}{1000000}$ths, from which it appears that mercury standards kept filled for a time remain quite as constant as a manganin resistance. For this reason standards XI. and XIV. will not again be filled, as the errors which are connected with such refilling will thus be avoided. The erection of new mercury standards will, however, be undertaken. The following table, extending over 16 years, shows that the average value, obtained from mercury standards XI., XIV., 106, 114 and 131, is practically constant, taking into account the observation error in the case of the mercury standard. There, therefore, appears to be no reason why the average value should be altered.

Table I.

	Int. ohms at 18°C.	Difference in 10^{-6} ohms.
November, 1893	1·001737	−2
January, 1895	37	−2
June, 1897	44	+5
March, 1903	48	+9
February, 1904	36	−3
March, 1905	34	−5
September, 1909	36	−3
	1·001739	

Opportunity was taken to determine from these measurements the values of a large number of manganin resistances between the temperatures of 12° C. and 26° C. The mercury resistance thermometer, which is made of quartz, and used in connection with calorimetric measurements, seems to retain its constancy of resistance quite well. Two similar 1-ohm resistances have therefore been constructed, which will be used as sub-standards in connection with the mercury and manganin standards.

In order to determine the effect of dampness on the 1-ohm manganin standards used in section I. three other 1-ohm resistances, which had first been carefully tested against the average value, were in July, 1909, permanently enclosed in an atmosphere of 50 per cent. humidity. A test on these coils after about three months showed that their value had varied about $\frac{1}{1000000}$th. This alteration is, however, within the limits of observational error. The year under notice was unsuitable for these observations, for specially dry weather, which might have had a great influence on the results, was waited for in vain. The observations so far obtained show that for corresponding coils alterations in humidity have no appreciable influence.

Silver Voltameter.—On account of certain earlier measurements on the silver voltameter, it seemed desirable (a special incentive being some work carried on in America in this direction) to discover whether the silver solution was influenced by the presence of organic substances. During some of the earlier measurements the anode was covered with raw silk, though at other times it was left bare. It may, therefore, be presumed that any small differences obtained between the two sets of readings would be due in the first instance to the use of an organic substance. This was, however, not the case when the relative measurements were carried out under the same conditions with and without silk. The mean difference between the values obtained in two cases was about half of $\frac{1}{100000}$th, while the mean observational error is about 12 times that amount.

Standard Cells.—Researches which were made on mercurous sulphate showed that when fresh preparations were used for making up standard cells, after being kept for several months in a dry place, the E.M.F. altered and became some 10,000ths of a volt too high. Further observations on this point show that when the freshly-prepared substance is stored under cadmium sulphate or in a vacuum no alteration in its conditions occurs, so that perhaps the oxygen of the air exerts a chemical action on the dry salt.

With the discovery of this phenomenon the last disturbing feature in the behaviour of the mercurous sulphate seems to have been found. It was already possible to obtain with accuracy preparations of the same E.M.F., but now their behaviour may be regarded as remaining permanently the same.

Thus it is now possible to begin the long-planned making of a great stock of standard cells, which will allow the practical unit of E.M.F. in the Reichsanstalt to be represented. For this purpose, the necessary chemicals—cadmium, cadmium sulphate, sulphuric acid, mercurous nitrate and nitric acid—were obtained as pure as possible from C. A. F. Kurlbaum, in Berlin, and then received a thorough testing in the chemical laboratory, in order that any harmful impurities might be rejected. Besides determining the purity of the substances by analysis the cadmium sulphate was re-crystallised twice and the mercurous nitrate once. Five preparations of mercurous sulphate were treated by the procedure described above, using solutions of sulphuric acid and mercurous nitrate of different strengths, and afterwards washed with water and concentrated cadimum sulphate. They were then preserved under concentrated cadmium sulphate solution. The cadmium amalgam was 12·5 per cent. strength and was prepared by melting.

The cells were of the well-known H-shape, with the form of leg used by the English National Physical Laboratory. By this means the electrodes covered with the salt could be kept in their places and the portability of the cells is thereby increased. After they have been filled, the cells were left open for some weeks to accelerate the welding together of the crystals, and were then sealed up. For storage and measurement they were placed in a large box for protection against the heat. Five groups of cells, corresponding to the five sets of mercury sulphate mentioned above were prepared, 67 cells in all, which, shortly after they had been put together, agreed within some $\frac{1}{10000}$ths of a volt.

Determination of the Absolute Ohm.—The idea of determining the absolute ohm by Lorenz's method was provisionally given up. Instead, attempts were made to determine it by geometric means and by absolute electric measurements of inductive coils. Afterwards it was determined by Wien's direct method and by the round-about way of comparing with a standard air condenser.

Heavy Current Laboratory.—After giving a list of the number and type of the various instruments tested during the year the report deals with the behaviour of electricity meters on variable loads. From theoretical data it was found that the readings of meters under such conditions were not falsified by the inertia of the moving system. This statement has been experimentally verified. During the past year a large number of continuous-current meters, in which the moving armature turns in the field of a permanent magnet and is in shunt across a resistance in which the main current flows, have been systematically tested. Such meters often do not fulfil the condi-

Digitized by Google

tions that require that the readings shall remain constant during a long period of load, but show inaccuracies or become gradually slower and slower as time goes on. This phenomenon is a natural result of the meter construction. For the potential drop in meters is very small (at full load only 1 to 1½ volts) and the armature voltage is small, so that small alterations in the contact resistance between commutators and brushes give rise to the above-mentioned inaccuracies.

J. Busch, in an article which appeared in the "Elektrotechnische Zeitschrift," Vol. XXX., p. 180, stated, as a result of observations and tests, that these inaccuracies were due to mercury vapour. This is specially important, as mercury vapour is very prevalent in those laboratories in which the behaviour of the meters is tested. From his tests it appears that so long as the brushes and commutators of the magnet motor meters do not come in contact with the mercury vapour the meters are very suitable for use. Mercury vapour causes a slowing up of the meter which increases as the load decreases. As these results did not agree with the experience at the Reichsanstalt, tests were undertaken on three new ampere-hour meters, which were designated I., II. and III. respectively. I. and II. were loaded continuously with their full current, and their inaccuracies at $\frac{1}{5}$, $\frac{3}{5}$ and full-load were measured at intervals of a week. I. was enclosed in a closed air-tight zinc box, while II., which hung close to it, was fitted with a protective covering.

During two months continuous using I. exhibited from the beginning inaccuracies, and at $\frac{1}{5}$ of full-load gave results varying up to 10 per cent., in spite of the fact that any effects due to mercury vapour were excluded. II., on the contrary, showed a falling off of 3 per cent. only during the first 14 days, and then remained constant, while removal of the protecting cap did not alter its readings. After it had been running for 10 weeks a small cup of mercury was placed in the meter, which was then again closed in. As the current warmed up the interior of the meter, the mercury vapour was given off at a fairly quick rate, so that the silver commutator became covered with a gray amalgam. In spite of this the meter ran for another eight weeks without showing any noteworthy alterations in its readings. As similar tests of meter III. gave the same results, it appears that the results obtained by Busch must be attributed to other influences.

Mercury Rectifiers.—The current which flows through the rectifier in the "unrectified" direction was accurately measured by its dependence on the form and loading of the rectifier. The results will be published. Six 10-ampere three-phase rectifiers were connected in parallel and were used for charging a large accumulator battery during the night, so that in the daytime as many batteries as possible were at disposal and the rotary transformer, which had hitherto been used for charging could be employed for other purposes.

Work on the Electrometer.—Researches on the electrometer were continued. As the electrometer is used, in the first instance, for alternating-current measurements a method was devised to find out whether the constants determined for the quadrants with continuous current held good for any desired phase alterations of the needle and quadrant voltages. It was found that this was the case with sufficient accuracy in all the cases undertaken. The results have been published, and at the same time the faults due to the capacity currents that flow through the electrometer section were discussed.

Researches are now being undertaken to obtain with more accuracy the values of the electrometer constants. In the general formula, where the discharge is proportional to

$$a_0v_0^2+a_1v_1^2+a_2v_2^2+b_0v_1v_2+b_1v_0v_1+b_2v_0v_2+\ldots,$$

v being the needle charge and v_1 and v_2 the quadrant charges, the relation

$$a_1-a_2=-b_1=b_2 \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (1)$$

may be taken as correct. It was then discovered that the constants in the two idiostatic cases (the needle being neither at earth nor at a high potential) do not always accurately correspond. The difference is, however, always less than $\frac{1}{1000}$th, as according to theory the idiostatic constants are proportional to a_1-a_2, and their differences can, therefore, be determined and equation (1) shown to be not accurately correct. But a simple alteration of the above connections may be used for testing the electrometer with alternating current to determine whether the difference between the idiostatic constants really exists or merely arises from observation errors. It appears that they may be present, for the differences obtained with alternating current and direct correspond with sufficient accuracy with those obtained by idiostatic measurements. The connections with alternating-current measurements are complicated, and care should be taken on this point when great accuracy is desired.

The different arrangements of connections which are used for alternating-current measurements in the Reichsanstalt for testing and other purposes have been published, special attention being paid to those methods which are employed in the testing of current and voltage transformers. The number of measuring transformers tested has steadily increased and is still rising. The transformers are tested at $\frac{1}{10}$, $\frac{1}{5}$ and $\frac{1}{2}$ of their primary current as well as at full load. A secondary load of 5, 15 and 25 volt-amperes is used and a power factor of 1 and either 0·8 or 0·5. The ratio of transformation is measured as well as the phase difference between the primary and secondary currents.

The measurement of the phase difference between primary and secondary current in the case of voltage transformers presented some difficulties at first. It appears that at high voltages the "tapped off" voltage is seldom in phase with the total voltage, though the division is effected by similarly built resistances. The differences are due to the capacity of the resistances from earth and from each other, and can be prevented by covering the resistances with conducting covers which must be charged to a certain known voltage.

The apparatus at present in the Reichsanstalt is sufficient for testing current transformers up to 1,000 amperes and voltage transformers up to 12,000 volts. It appears, however, that practice will require tests on apparatus carrying greater currents and voltages, but tests on them cannot unfortunately be made in the space available at present.

(To be continued.)

THE WOOD PULP AND PAPER MILLS OF THE ANGLO-NEWFOUNDLAND DEVELOPMENT CO.

A LARGE HYDRO-ELECTRIC SCHEME.

Introduction.—It was remarked, we believe by Carlyle, that his was an age of paper. And if this statement were true then how much the more true is it at the present time, when every profession and trade in the land has usually many organs devoted to its interests, while even an erotic amusement (such as roller-skating) cannot develop without its representative journal. It is, therefore, not surprising to find that the original sources of news paper are becoming somewhat exhausted, and that efforts are made to obtain the necessary raw materials from new sources. These attempts have been in the main successful, for wood-pulp treated with certain chemicals is now used in prodigious quantities as the basis of much of the paper used in modern newspaper production. This being the case, it is necessary for pulping mills to be erected near the wood supply, as the pulp is, of course, more easily transported than the wood. Turning to another side of the paper-making question, it is found to be an economical advantage for our great daily and weekly papers, with their huge circulations, to make their own paper, and this has recently resulted in the formation of the Anglo-Newfoundland Development Co., an offshoot of the Amalgamated Newspaper Co. of London, and whose object is to provide the various companies in that combine with its cheaper quality papers on reels.

An extensive site for the paper mills was chosen on the island of Newfoundland, near St. John's and Grand Falls, and here large wood-pulp and paper-making machines, driven by hydraulic turbines with an aggregate capacity of 23,500 H.P., have been erected. The conditions were specially favourable for the erection of such plant, first, because of the existence of adequate water-power with a sufficient fall (nearly 100 ft.), conveniently situated in respect to the mill buildings; and, secondly, from the existence of a vast area of timber-covered land, which could be transformed on the spot into wood-pulp, and subsequently fed to the paper-making machines for paper.

General Arrangement of Hydraulic Works and Buildings.—The Exploits River is the source of power for the works. The river flows over a series of declivities which extend for nearly half a mile. At the top of these declivities the stream makes a bend, between the beginning and the end of which there is a fall of 112 ft. At the highest point a solid concrete dam 882 ft. long has been built, its width being 24 ft. at the bottom, and gradually diminishing to 6 ft. at the top, whilst the height varies from 20 ft. to 25 ft. Wing dams increase the length to 1,400 ft. A forebay is provided with eight gates each 12 ft. high × 8 ft. wide. The forebay in this case is a basin about 150 ft. square and 20 ft. deep, and the water flows from this basin to the power house through steel racks and then into two steel pipes, 15 ft. in dia. and 2,150 ft. in length. A general view of the exterior of the power house is shown in Fig. 2.

270 ft. long × 60 ft. wide × 50 ft. high, being lighted from above by skylights. At the northern end are erected two 2,500 H.P. dynamos, which supply energy for light and power to the entire works, the remainder of the building being occupied by turbines operating the pulp grinders. There are three turbines in the generating room and four double pulp grinders turbines in the grinding room, each of these latter providing the power for six grinders. Each of the 24 grinders has an output of about 10 tons of dry pulp per 24 hours, or 240 tons of pulp per day. Ultimately the total output is expected to reach 2,500 tons per week of paper and pulp. Two systems of ventilation are provided, one natural, through a concrete shaft 16 ft. × 16 ft. at the end of the building, and extending to the roof, which in the autumn and winter is sufficient for the purposes. In the summer and spring a 90 in. blower is used as an addition. The pipe line from the water source is made up of two steel pipes, each 15 ft. in diameter and 2,150 ft. long, which connect with the turbine house by means of a cross tube 10 ft. in diameter. One of the principal pipes diminishes from 15 ft. to 10 ft. diameter, and supplies the generator turbines, while the other pipe forks into two branches of 10 ft. 9 in. diameter, and feeds the grinder turbines. The thickness of the 10 ft. tubes is ½ in., the rivetting being single for the circumferential seam and double for the longitudinal seam. Attention may be directed to the simple nature of the expansion joint, which is shown in detail in Fig. 3. It may be mentioned in this connection that with full load on the plant the water velocity in the principal pipes amounts to 8·25 ft. per sec.

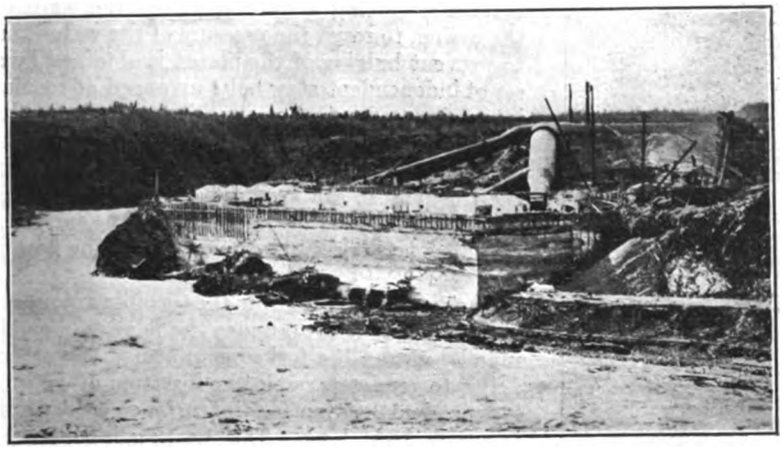

FIG. 2.—GENERAL VIEW OF THE EXTERIOR OF THE WORKS, SHOWING PIPE LINE.

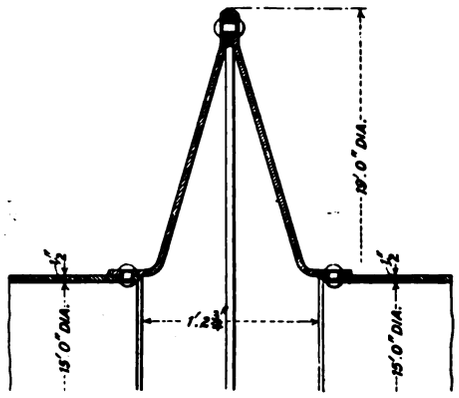

FIG. 3.—VIEW OF EXPANSION JOINT USED ON PIPE LINE.

Turbine Plant.—The turbine plant may be divided into three principal parts: (1) The sets driving the pulp grinders, (2) the sets driving the generators, and (3) the sets driving the oil pumps. Four turbines, each capable of developing 4,000 H.P. at 224 revs. per min. are used for the production of ground pulp wood. These operate under a head of 105 ft. with a discharge of 415 cubic ft. per sec. Each turbine is coupled on both sides to three large wood grinders, each requiring about 700 H.P. The raw material is brought into these grinders through a canal running through the centre of the turbine house. Into this course the round timber, cut into suitable lengths, is floated from outside. The output of pulp is led away through two channels which run round the walls of the turbine house and connect with the wood grinders by means of transverse channels.

The second turbine plant drives the special machines installed in the paper factory, which is situate some distance from the power station. It was therefore decided to use electric transmission, and for this purpose the power station is provided with three turbine generator units, each capable of developing 2,500 H.P. at their normal speed of 375 revs. per min. These sets operate under a head of 105 ft. and have a discharge capacity of 263 cubic ft. per sec.

The oil pumping plant installed, and for which the third set of turbines is employed, is for the supply of oil under pressure, which serves not only for the lubrication of the grinder turbines, but also for the generating turbines.

Pulp Grinding Plant.—The main inlet pipes which feed the 4,000 H.P. turbines are branched, each branch pipe connecting up two of the double 4,000 H.P. machines. Two main inlet pipes, therefore, suffice for the four turbines. The arrangement of the turbines as double units with double spiral inlets is that usually employed. Butterfly valves are used for shutting off the supply, each turbine being provided with two of these valves, which are so connected with each other that they can only be opened or closed simultaneously. The object of this arrangement is to eliminate axial shear stresses on the turbine shaft as far as possible. The outlet pipes from the turbines are of spiral arrangement, as the two concrete draft tubes attached to the two double quarter bends of the turbines diverge in opposite directions, due to the fact that two of the 4,000 H.P. turbines are behind each other in the direction of the outlet. The draft tubes have, therefore, a double curved centre line. The construction of the turbine is notable in many respects, and especially as to the distributing and regulating apparatus. The runner blades are of sheet steel, and surrounding the runner is the distributing apparatus,

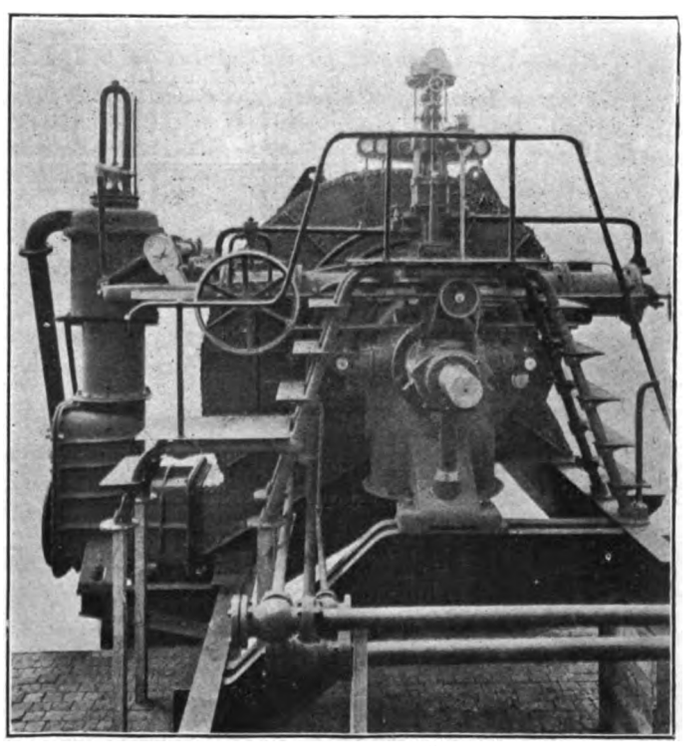

FIG. 4.—END VIEW OF A MAIN DOUBLE GRINDER TURBINE.

Digitized by Google

which is arranged with 20 movable guide vanes. These, along with the crank pins which project through the guide wheel cover on both sides, are forged in one piece. The crank pins are set in the casing cover in removable bronze bushes, packing being effected by stuffing boxes fitted with screw caps At the

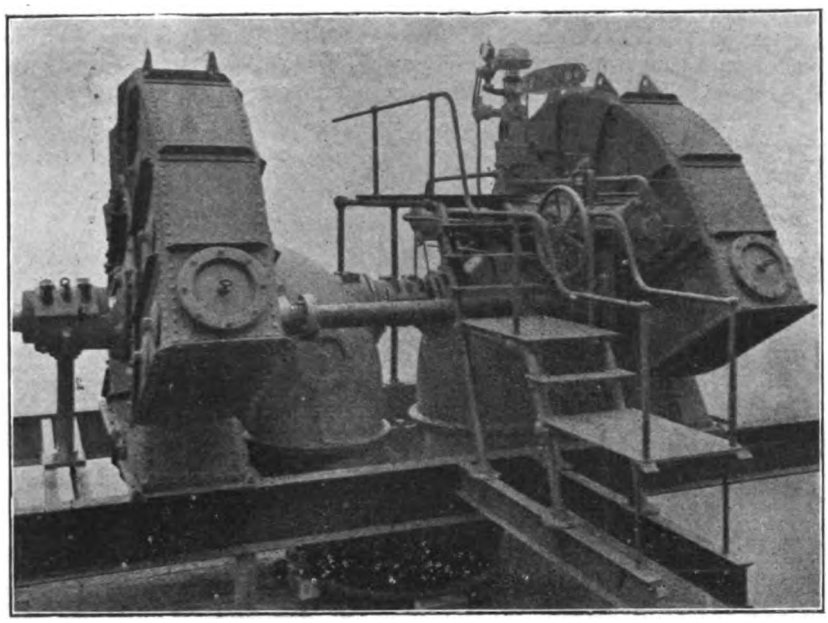

FIG. 5.—ONE OF THE MAIN DOUBLE GRINDER TURBINES.

place where connection is made with the regulating lever and the movable vanes a bushed outer bearing is provided, which is so constructed that it forms with the inner bearing a single connection between the casing covers, in order to take up their reaction pressure. This construction provides for easy dismounting and renewal of the bearings. Both inner and outer bearings are fitted with Stauffer lubricators. The connection of the regulating ring with the ends of the regulating lever is effected in the manner shown in Fig. 4.

The steel regulating ring is in one piece, and is movable in an axial direction over a drum seat by means of sliding blocks, which at the same time serve as stroke limits and secure the ring against axial displacement. The regulating movement of the governor pendulum and of the relay, or servo-motor, is communicated to the regulating ring by a pair of levers fixed on opposite sides of the turbine, as shown in Fig. 4. The inner surfaces of the guide wheel cover, which is the part most often in contact with the flowing water, are fitted with removable cast-steel piston or junk rings. The system of bracing adopted between the walls of the casing, to resist the pressure of the water and to prevent bulging of the plates, is obtained by a set of independent stay bolts arranged at regular intervals, and at the opposite end by bolts through the drum, which latter lies outside the guide blades. The bolts run through holes in the ribs, and so are kept out of contact with the water. Owing to their special shape the enclosing ribs offer no appreciable opposition to the flow of the water.

The discharge pipes from the turbines are simply curved and joined up under the floor to a single pipe by means of a forked connection, the object being to render possible the insertion of a third independent bearing for the turbine shaft, which is nearly 25 ft. long. This bearing is supported in the same manner on both the two quarter-bend discharge pipes, and can be readily moved out of its place. The two bearings fastened on the guide wheel cover are of the usual bracket type, though each has a special pedestal support. All three bearings are fitted with removable babbited bushes, and one of the bracket bearings is arranged as a collar thrust bearing. In order to allow the withdrawal of a single runner from the shaft without dismounting the grinders the grinder shaft is connected to the turbine shaft by means of a special coupling, and these when loose leave the necessary space free between the shaft ends to allow of the guide wheel cover and the runner being taken out. All the other parts of the turbine, including the

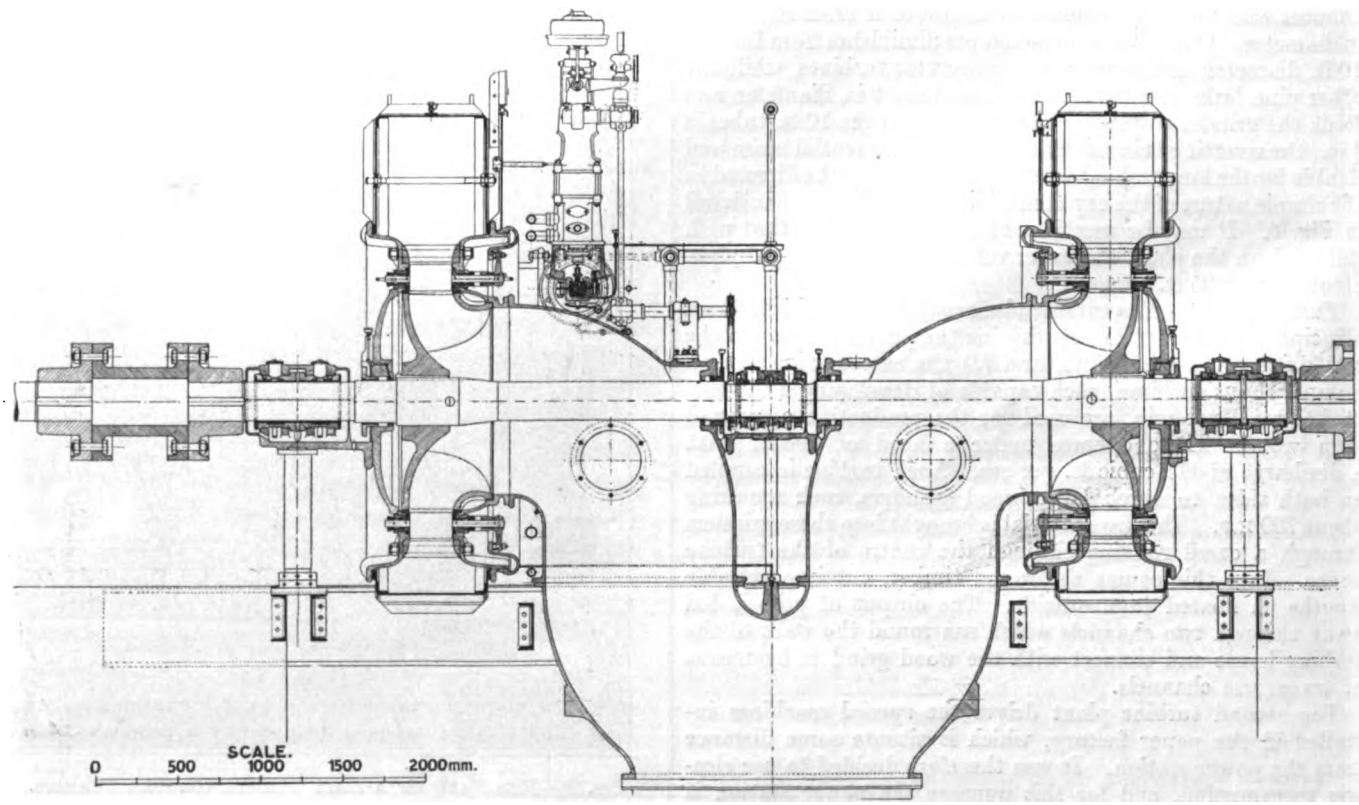

FIG. 6.—DETAILS OF DOUBLE GRINDER TURBINE.

Digitized by Google

shaft, can be dismounted in this way without interfering with the three grinders coupled to each side of the double turbines.

Governing is effected by a pendulum governor and an assistant servo-motor. The latter sets in operation a principal servo-motor, the piston of which transmits motion direct to the regulating ring. The oil pressure supply is used in connection with this apparatus. The action of this is as follows: The rocking movement of the balance weight is changed into a motion in the direction of the pendulum axis. This operates the pendulum sleeve by means of the valve rod and front distributing rod. With this rod is connected a piston which serves at the same time as a distributing valve to the principal servo-motor, and opens the distributing ports below the cataract valve. Thus, by the upward movement of the piston, or sleeve, the delivery chamber is brought into communication with the discharge chamber.

The opening of the ports establishes connection with the principal servo-motor, and movement of the main piston is thus effected. This movement is in turn transmitted to the regulating ring by the pair of levers shown. To ensure that the regulating movement is completed at the proper time the valve passages must, of course, be closed again, and this is effected by a vertical motion which is imparted to the valves by a horizontal slanting surface formed on the piston rod of the principal servo-motor. The return or closing motion of the valves is effected by hand, or by an electric motor, while the machine is in motion. This method of governing gives a high degree of sensitiveness.

The principal servo-motor, consisting of two cylinders connected by a bayonet casting, is bolted to the turbine, and on the bayonet the assistant servo-motor and pendulum governor are fixed. The two pistons of the principal servo-motor are connected with each other by a common piston rod, to which are pinned the forked heads of the main regulating levers. The latter are in turn connected with the main regulating shafts, by which the motion of the pistons is transmitted to the cranks of the regulating ring. All drip oil is collected and brought back into the oil reservoir through a return pipe. The pendulum is driven through worm gearing in connection with a silent Morse chain. Besides the automatic regulation, hand gear can also be used. This arrangement, however, is only used when the oil pressure falls short.

The control apparatus, all of which is so situated as to be within easy reach of the operator, can be manipulated without leaving the machine platform, and the reading instruments are all mounted in one frame, enabling the number of revolutions, pressure in the turbine, pressure in the regulating cylinders to right and left, and the vacuum in the draught pipes to be readily observed. The two turbines possess one bridge in common, this serving the novel purpose of also spanning the canal running through the works down which the wood is floated to the grinders. A general view of one of the main turbines is given in Fig. 5, while Fig. 6 shows the various details of these machines.

(To be concluded.)

THE TESTING OF TRANSFORMER REGULATION.

BY C. V. DRYSDALE, D.SC.

Summary.—Where transformers are run in parallel it is important that all the transformers should have similar regulation curves. For inductive loads the curves are not similar, unless the ratio and phase displacement are the same for each transformer at the same fraction of full load. The usual short-circuit test is not very suitable for obtaining these data, as the instruments are generally working at the bottom of their range, and a small error in the indications makes a large error in the final result. The author therefore proposes a method in which the voltage of the transformer under test is compared with that of a second transformer of approximately the same ratio on open circuit. Results of tests by this method are given.

Whenever large transformers are banked together for power transmission it is of the greatest importance that their regulation curves should be similar, as otherwise some of them may be seriously overloaded while the others are running comparatively light. Two examples of this were given in the "Electric Club Journal" of June and July, 1905. In one of them a bank of transformers had been installed and were found so satisfactory that a repeat order was given. In the meantime, however, the constructors must have improved the regulation of their transformers, and when put in parallel with the old ones the new transformers burnt out after a few hours, owing to their taking nearly the whole of the load.

As is well known, the regulation of transformers cannot be satisfactorily determined directly by measurement of the voltages at various loads, owing to the smallness of the drop in comparison with the working voltage. Moreover, the effect of loading a transformer on a non-inductive load is not only to reduce the voltage from V_0 to V (Fig. 1), but to make it

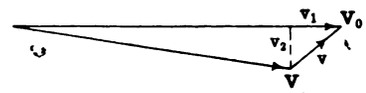

Fig. 1.—Transformer Voltage Non-Inductive Load.

lag; and the difference v_2 is as important as the drop v_1, since it represents the drop on fully inductive load, as in Fig. 2. In order that the transformers should share the load equally under all circumstances, the ratio and phase displacement must be the same in each at the same fraction of full load.

The direct test being unreliable, it has generally been sought to predict the regulation by measurement of the equivalent resistance and reactance of the transformer, derived from the short-circuit test. For this purpose one of the windings of the transformer is short-circuited, and alternating current passed through the other, the P.D. v, current C and power w being noted. Then the equivalent impedance is $I=\frac{v}{C}$, the equivalent resistance $r=\frac{w}{C^2}$, and the equivalent reactance $x=\sqrt{I^2-r^2}$.

This test, though simple in principle, is not always easy in practice. As in a good transformer the total full load drop is

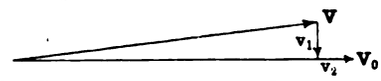

Fig. 2.—Transformer Voltage Inductive Load.

not more than 2 per cent., the voltmeter and wattmeter are generally working at the bottom of their range. Further, if as in many cases, the reactance is considerably smaller than the resistance, the resistance is nearly equal to the impedance, and a very small error in the measurements makes a considerable error in the reactance. It is easily proved that the percentage error in the reactance is $1+\frac{r^2}{x^2}$ times the percentage error in the P.D., current, or power, when the reactance is relatively small, and if $r=3x$ an error of 1 per cent. in the instruments causes an error of 10 per cent. in x, as is obvious from

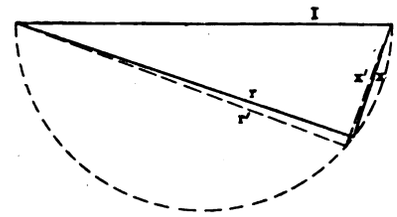

Fig. 3.—Error in Reactance produced by 1 per cent. Error in Resistance.

Fig. 3. When this is added to the unfavourable conditions under which the instruments are used, it will be seen that the test is not so reliable as might be thought. It must also be remembered that the resistance and reactance so determined are taken with the iron at a very low induction compared with the normal, and that the reactance may consequently be higher than when the iron is more saturated, as it is under working conditions.

When testing some even-ratio transformers for ratio and phase displacement as instrument transformers,* it was seen

* The Electrician, Vol. LVIII., p. 160. "Phil. Mag.," July, 1908.

Digitized by Google

that a modification of the method would serve for testing the regulation of large transformers of any ratio under actual practical conditions with considerable accuracy. The basis of the method is to compare the voltage of the transformer under test with that of a second transformer of approximately the same ratio on open circuit. For the measurement of the difference of the voltages a wattmeter is employed, in which the moving coil circuit is connected to the constant voltage of the auxiliary transformer, while the main coils, in series with a non-inductive resistance, are used as a low resistance voltmeter. In order to measure the reactance or phase displacement with greater accuracy, a condenser can be inserted in the shunt circuit, as described in the previous communications.

The connections for the test are shown in Fig. 4, in which the transformer under test P_1, S_1 is shown connected to the supply mains and to a load exactly as in service, and in parallel with an auxiliary transformer, P_2, S_2, of approximately the same ratio. The size of the auxiliary transformer is quite immaterial, but if a bank of transformers is being made up any one of them will serve the purpose. If the secondary circuits of the transformers S_1 and S_2 are connected as shown, the P.D. between the two lower conductors will be the vector difference between the voltage of the auxiliary and test transformer. The main coil of the wattmeter W is connected between these two lower leads with a non-inductive resistance, R′, in series with it, and thus carries a current proportional to the vector P.D. v above referred to, while the moving-coil circuit is connected to the secondary of the auxiliary transformer, the voltage of which is conveniently kept constant by maintaining the supply voltage constant. The non-inductive resistance R in the wattmeter shunt circuit is, however, connected to a change-over switch which puts either this resistance in series with the moving coil or replaces it by a condenser, K. If a little care is taken in arranging the circuits beforehand the measurements can be made quite simple. The best way, as a rule, is first to select a suitable condenser for the moving coil circuit of, say, 1 mfd. or 0·5 mfd. capacity. The capacity reactance of this condenser is then $\frac{10^6}{Kp}$, where K is the capacity in microfarads and $p = 2\pi \times$ frequency. In the test described below, a 0·5 mfd. condenser was used with a frequency of 50 ∿, for which $p = 314{\cdot}2$. Hence the capacity reactance $= \frac{10^6}{0{\cdot}5 \times 314{\cdot}2} = 6{,}360$ ohms. The resistance of the moving coil of the wattmeter was 620 ohms, so that the impedance of the circuit with the condenser in series was $\sqrt{6{,}360^2 + 620^2} = 6{,}390$ ohms, or practically the same as the capacity reactance. If we deduct the moving coil resistance (=620 ohms) from the above we have 5,770 ohms, and if the non-inductive resistance R is adjusted to this value the current in the shunt circuit will be of the same amount whether the resistance or condenser is in circuit.* If we now have a small transformer which has a known ratio of, say, 10 to 1, and connect it to the secondary of the auxiliary transformer, then we know that if the P.D. of the auxiliary transformer is 100 that of the secondary of the small transformer is 10 volts and in phase with it. (The writer has shown that the P.D. ratio and phase of voltage transformers on open circuit is very closely correct.) We may now apply the main coils of the wattmeter in series with its non-inductive resistance to the terminals of the small transformer, and adjust this resistance until we get a convenient reading. In the experiment below a torsional wattmeter with 500 divisions on the torsion head was employed, and the resistance in series with the main coils was adjusted until with 100 volts on the shunt, and consequently 10 volts on the secondary of the small transformer, a deflection of 500 divisions was obtained, or of 50 divisions per volt. At the same time, the shunt circuit was changed over to the condenser, and a reading of 62·5 divisions was obtained. Had the change over to the condenser changed the wattmeter current into exact quadrature, there should have been no deflection in the second case, and the fraction $\frac{62{\cdot}5}{500} = 0{\cdot}125$ is the tangent of the angle by which the shunt current departs from quadrature, or tan θ in Fig. 5. This tan θ should have been equal to the resistance of the moving coil, divided by the capacity reactance $= \frac{620}{6{,}360} = 0{\cdot}0975$ if the condenser had no absorption, the difference $0{\cdot}125 - 0{\cdot}0975 = 0{\cdot}0275$ being approximately the power factor of the condenser. These preliminary calculations and adjustments seem complicated, but when once understood can be performed in a few minutes. When they have been done, and the voltage and frequency are kept approximately constant, the wattmeter becomes a direct-reading voltmeter, which, when the resistance R is in the shunt circuit, reads the component v_1 of any voltage v in phase with the "exciting voltage" on the shunt (in this case the voltage of the auxiliary transformer), while with the condenser in circuit it reads the component v'_2 in phase with the condenser current. As will be seen at once from Fig. 6, however, the quadrature component $v_2 = v'_2 - v_1 \tan\theta$ approximately, and, since tan θ is known, the two components are at once given.

It goes without saying that the instrument so set up is suitable for all tests in which inductances or alternate-current vectors are required, and, as a matter of fact, it gets over the difficulty above mentioned of accurately measuring the reactance in the short-circuit test, as will be seen below.

The tests given below were made at the Northampton Institute on two 2 k.v.a. 2,000–100 volt transformers (A) by the Electric Construction Co. and (B) the Brush Co., loaded on a non-inductive resistance. The adjustments having been made as described above, the following tables for the first transformer are almost self-explanatory.

Table I. gives the results of the regulation test by the method above described. The two deflections D_1 and D_2 are those of the wattmeter with the resistance and condenser respectively in the shunt circuit. On dividing D by 50, the number of divisions per volt, we get the P.D. v_1', which is the component of the difference of the voltages of the two transformers in phase with the P.D. of the auxiliary transformer. In this case the first reading of $D_1 = 37{\cdot}5$ divisions shows that the P.D. of the auxiliary transformer was 0·75 volt lower than that of the test transformer on open circuit; and hence the real drop v_1 of the test transformer below its no-load voltage is obtained by adding 0·75 volt to each of the values of v_1' in the fourth column. The value of v_2 is given by $\frac{D_2 - 0{\cdot}125D_1}{50}$, while v is obtained in magnitude and phase from v_1 and v_2. By dividing the values of v_1 and v_2 respectively by the current C we get the equivalent resistance and inductance of the transformer which are shown in the last two columns, and are seen to be very fairly constant. The curves A, Fig. 7, show the regulation on non-inductive and inductive load of this transformer deduced from their results, while those marked B are similar curves for the other transformer, and clearly indicate the difference between the designs.

„ „ (regulation test)	0·040	0·15

In Table II. the results of a no-load test on the first transformer are given, while Fig. 8 shows curves for the two transformers. These tests call for no comment, except that as the condenser was available, the two components of the no-load

Digitized by Google

current were measured in a similar manner to the components of the P.D. in the regulation test. In the case of transformer A the magnetising and core loss currents are so nearly equal that it should be almost equally accurate to determine the magnetising current by the formula $\sqrt{W^2-w^2}/V$, or by the condenser; and it will be seen that the two values so obtained are very fairly concordant, except at high voltages, where the greater saturation of the core probably considerably distorts

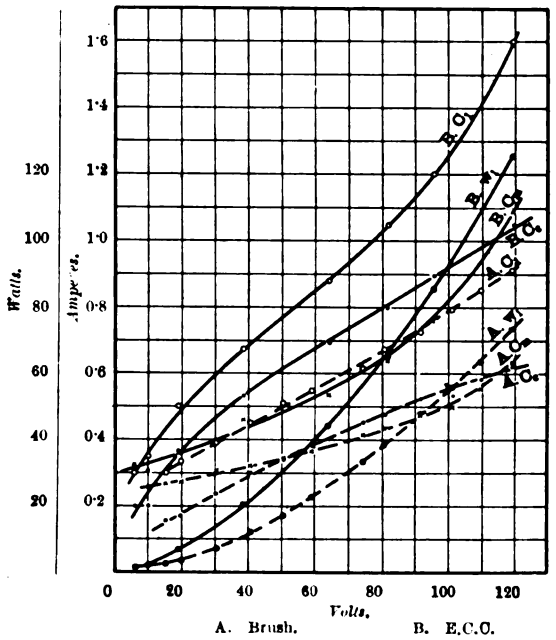

Fig. 8.—No-load Tests.

the magnetising current. The agreement is, however, sufficiently close to establish the reliability of the condenser method for the regulation and short-circuit tests.

Table III. and the accompanying curves, Fig. 9, apply to short-circuit tests on the transformers, the condenser being again employed. The equivalent resistance w/C^2 is obtained without any difficulty, but is so nearly equal to the impedance V_1/C_1 that the accuracy of measurement of the reactance $\sqrt{I^2-r^2}$ is very small. As will be seen, the average value of

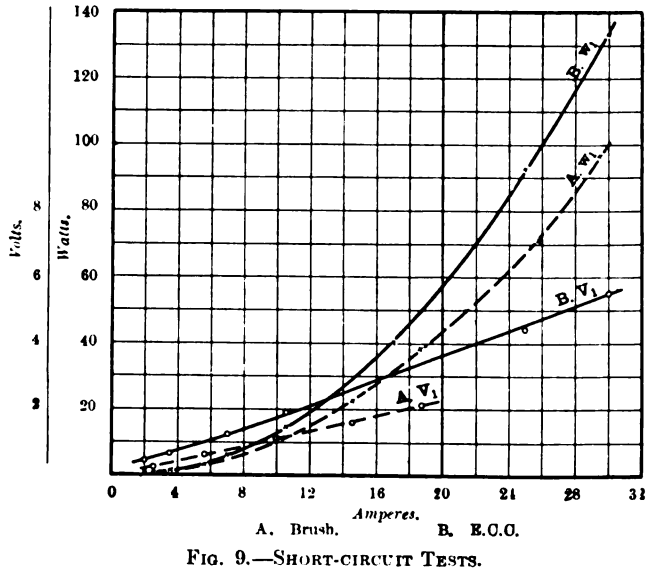

Fig. 9.—Short-circuit Tests.

the reactance comes out as about 0·038 ohm, while, according to the condenser test, it should have been about 0·057 ohm, or 50 per cent. greater.

Finally, Table IV. shows the comparison of the results obtained by the various tests. It will be seen that the values of the equivalent resistance obtained from the short-circuit test and the new regulation test are almost identical in the case of transformer A. In the case of transformer B the regulation test gives a higher value of the equivalent resistance. As to the reactance, in both transformers the value obtained from the regulation test is only 70 to 80 per cent. of that given by the short-circuit test, which must be attributed to greater core saturation, and shows that wherever close regulation tests are necessary some such method as that here described is required.

In conclusion, it should be stated that this test is obviously applicable in conjunction with loading-back devices; and that the whole of the tests could be very rapidly made by the alternate-current potentiometer described by the author,* in which the magnitude and phase of the P.D. and current vectors can be immediately read off.

The author's thanks are due to Messrs. A. C. Jolley and H. Gerrard for assistance in the tests, and to Mr. A. E. Burgess, B.Sc., for working out the results.

THE EXAMINATION OF WATER BY ELECTRICAL METHODS.†

BY W. POLLARD DIGBY.

Summary.—The author first describes a form of conductivity tube which he has devised for use, not only in the physical laboratory, but in everyday engineering work. It furnishes information as to whether condensers are leaking, the amount of the leakage, the amount of priming arising in boilers, and the control of oil eliminating and water softening plants. Details of tests carried out at various power stations are given.

That water in its varying degrees of impurity is anything but a medium of constant value comes within the experience of all engineers, and hence frequent resort is made by the engineer to the analytical chemist for advice and assistance. However, this is not always done as often as might be desired, and a variation in the nature of a supply may take place with no visible change in the appearance of the water, but yet with such changes in the constituents as would render the water quite unsuitable for boiler feed purposes. The author's object in the present Paper is to point out the value of simple tests made *in situ* as safeguarding the owners of boilers from such happenings, and as determining when the analytical chemist should be employed. These tests, however, are not intended in any degree to supersede the analyst, but may serve to determine when detailed analyses are necessary by indicating changes in the impurities in the water. The method resolves itself into a determination of the conductivity of the liquid at any predetermined temperature and a comparison of such determinations with the known values of analysed samples. Any marked variation from the normal should be followed by a further analytical examination.

Measurements of specific resistance of water have hitherto demanded careful laboratory determinations. The method most widely known, viz., that of Kohlrausch, depends upon the employment of the Wheatstone bridge, with an alternating current and a telephone receiver in place of the galvanometer used in ordinary resistance measurements. This method, while indubitably one of precision in the hands of those highly trained, permits of varied results from different experimenters. Another laboratory method provides for carrying the liquid to be measured in a glass tube forming a secondary short-circuited coil of a static transformer. While this device is visual rather than aural, the delicate instruments necessary, together with the calculations required, relegate this most ingenious apparatus to the physical laboratory. For determinations of the conductivity of liquids or electrolytes the apparatus to be employed should not necessarily involve the use of alternating currents, and a measuring apparatus fitted with a scale should indicate conductivity in reciprocal ohms or reciprocal megohms as a function of the current furnished by the generator. On the electrochemical side the effect of polarisation has to be limited. This can be effected by cir-

† Abstract of an original communication accepted by the Council of the Institution of Electrical Engineers for publication in the Journal.

Digitized by Google

culating the liquid under examination past the electrodes at such a rate as to wash away any adherent film of hydrogen bubbles.

An apparatus embodying these features has been devised by Mr. C. W. V. Biggs and the author, and has been used on all the experiments and tests described in this Paper. The original type consists of a straight glass tube so constructed as to hold the equivalent of a body of liquid 10 cm. in length and 1 sq. cm. in sectional area, the liquid being contained between platinum electrodes attached to plugs of ebonite fixed in cups which form enlargements of the ends of the tube. The electrodes are suitably connected to terminals in the ebonite ends, and are capable of being adjusted. The liquid to be tested is introduced into the main tube through a small tubulure, rising at an angle from the middle of the upper part; and when tested is run off through a small tube furnished with a tap attached to the middle of the lower part. At each end of the upper surface of the body tube a vent tube is attached, inclining to the middle

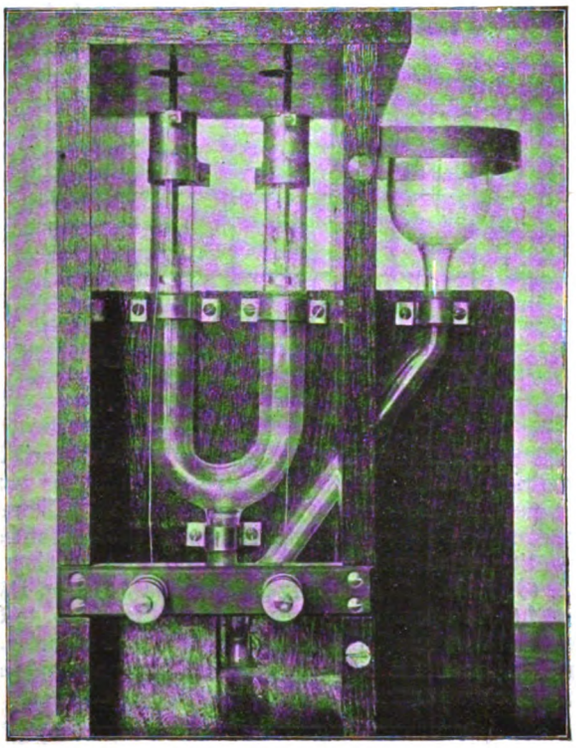

Fig. 1.

of the main tube, and the two unite at a height of about 2½ cm. above it, with a short vertical outlet. The arrangement is shown in Fig. 1.

Manifestly such a piece of apparatus is hardly suitable for use outside the laboratory. The form for practical work consists of a glass U tube, to which is attached at the lowest point of the bend the tube brought from the filling funnel, whilst the outlet, controlled by a glass tap, is joined to the inlet at its lowest point. Near the extremities of the limbs of the main tube overflow ways are sealed on, and terminate in indiarubber tubes grouped with the lower outlet. The form and arrangement of the electrodes are especially designed to minimise the disturbing effects of polarisation and other difficulties inseparable from the original type of tube. The electrodes are open cylinders of platinum, about 9 mm. in diameter and 3 mm. in height, connected by three equi-distant platinum wires to stout brass glass-covered rods passing through the brass covers which are connected to the terminals. The dimensions of tube and electrodes are such that the equivalent of a body of liquid having a length of 10 cm. and a sectional area of 1 sq. cm. is obtained. The apparatus is mounted on a strong wooden support carrying a thermometer, and the whole is contained in a lock-up portable case (Fig. 2).

The most convenient instrument for measuring the conductance is the "conductance meter" made for use with the tube by a well-known firm which the author has entrusted with the manufacture of the apparatus. It resembles the familiar "megger," but is furnished with a scale graduated in reciprocal megohms and ohms, and with a tube of sectional area one-tenth the length it gives readings of one-tenth of the specific conductivity—equivalent to the reciprocal of 10 times the specific resistance. Correction for variation of temperature for water containing less than 1 per cent. of dissolved salts may be made with sufficient accuracy by taking the coefficient as 2·19 per cent. per 1°C., as referred to 20°C.; but above 38°C. such correction is not reliable owing to complications arising from disengagement of small quantities of dissolved gases and also from physico-chemical action.

At the outset the author experienced considerable difficulty in determining standards for comparison. Distilled water, obtained either from the laboratory of the analytical chemist or from the shop of the pharmaceutical chemist, cannot be regarded as a standard product. Absolutely pure distilled water has probably never been obtained. The best that the author has heard of was a special sample prepared by Kohlrausch, which had a value of 0·043 reciprocal megohm at 18°C. This was prepared by distillation *in vacuo*, and collected in an especial glass cell which had been kept for 10 years full of distilled water. Of samples passing through the author's hands, good distilled water has varied in its specific conductivity from 4·0 to 1·362 reciprocal megohms for laboratory distilled water, and for distilled water from surface condensers the best has been 3·3 reciprocal megohms. As a general standard of comparison, good distilled water might possibly be defined as possessing a specific conductivity of 3·3 reciprocal megohms, or a specific

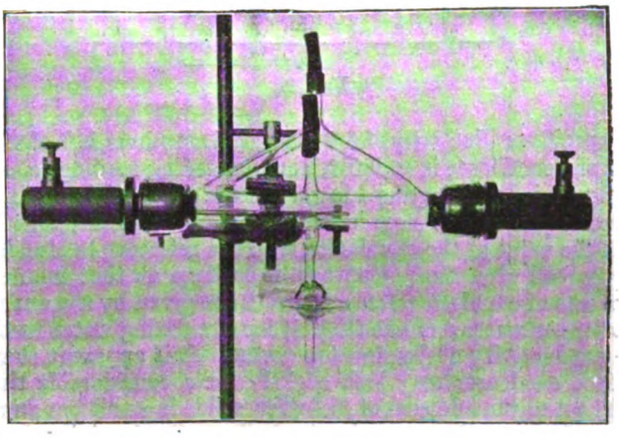

Fig. 2.

resistance of 300,000 ohms at about 20°C., this value representing an approximate average value of the output of the Liebig condensers in the laboratory of one of the author's friends, and also representing the best practice from central station surface condensers that has come under the author's notice.

All books on physics refer to the effect of minute traces of impurities as greatly increasing the conductivity of distilled water. The author has noticed that shaking 30 cc. of good distilled water in a *clean* 50 cc. stoppered flask for 30 seconds has resulted in doubling the conductivity, probably owing to the absorption of impurities from the imprisoned air. Some typical results of the author's investigations on the effect of minute traces of sodium chloride, sodium carbonate and calcium sulphate are given in the Paper. It must be remembered that the method of testing does not discriminate between different impurities.

Feed Water.—Fig. 3 shows the relation between degrees of hardness and conductivity of water when that hardness is due solely to calcium carbonate. It is apparent that conductivity tests also permit the checking of the operation of evaporators for make-up purposes at sea, or for the supply of distilled water for hydraulic gun mountings, and further provide a check on the operation of surface condensers in all places.

Condenser Tightness and Priming.—Given a boiler free from priming, a single conductivity measurement of the water pass-

Digitized by Google

ing from the condenser to the hot well will indicate the tightness of the condenser tubes. It will be urged that any impurities indicated may after all be due to boiler priming. Any doubts upon this score can be readily settled. All that is necessary is to take, say, four or five samples (after running long enough to wash out possible impurities from the steam ways), one with the engine or engines turning round light, and other samples at stated points upon an increasing load. Then if the conductivity is high in the first reading, being anywhere well in excess

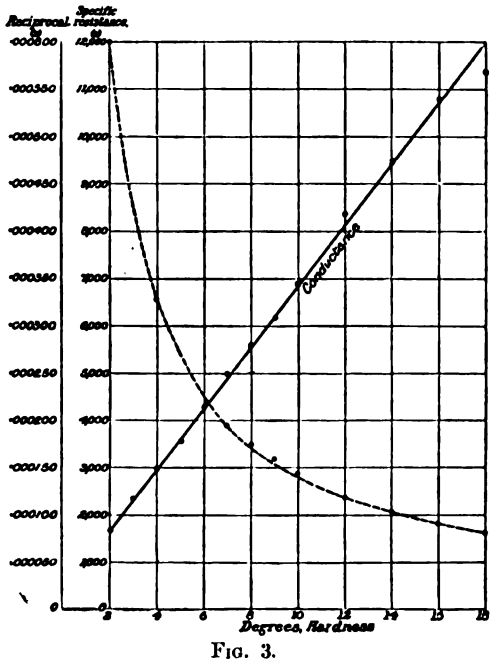

Fig. 3.

of a specific conductivity of 3·0 reciprocal megohms, it is obvious that the condenser is at fault, and succeeding readings should confirm this by indicating a lower specific conductivity. If the approximate rate of flow is known at any moment, together with the value of the circulating water, a reference to standard curves will give the percentage of leakage at that moment. Two sets of standard reference curves are given by the author, one for sea water and one (Fig. 4) for circulating water having the conductivity of London tap water. It is apparent that a surface condenser may leak slightly for a considerable time, and lead to the addition of dissolved solids in small but cumulative doses to the water in the boiler. Conductivity determinations, while indicating when overhauling is necessary,

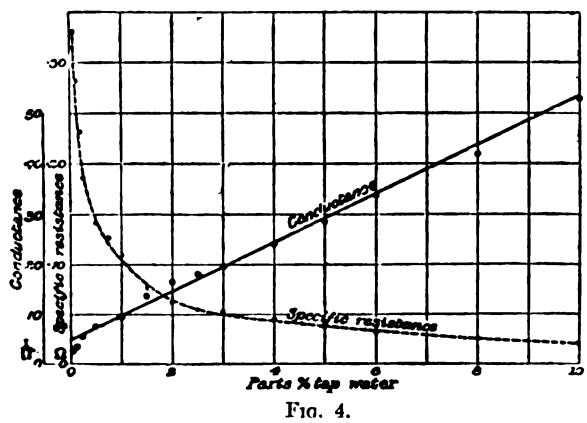

Fig. 4.

may save unnecessary examinations. If, on the other hand, the conductivity of the hot-well water, initially low, rises as the load on an engine increases, the only possible deduction is that the boiler is priming.

The grade of the water within boilers is subject to wide variation. The author has found the specific conductivity of water in boilers to vary from 11·1 reciprocal megohms to more than 90,000 reciprocal megohms. It therefore becomes necessary for each test for boiler priming to plot a special curve giving the conductivity of various portions of the water actually in the boiler mixed with standard distilled water. Fig. 4 is a special curve showing the conductivity of varying proportions of West London tap water and distilled water.

Tests have been carried out by the author and his staff on several typical installations of boilers. In each case, in addition to an initial checking of the tightness of the condenser, and the determining of the value of the water in the boiler, the following readings were obtained: (*a*) Height of water in gauge glass; (*b*) evaporation during period; (*c*) load on station in kilowatts; (*d*) conductivity of sample obtained; (*e*) percentage of priming deduced from (*d*). Inasmuch as this is the first occasion upon which a series of priming tests have been made upon such an exhaustive scale as was employed, and as the method involved permitted of an exactitude of measurement of priming not hitherto available, the author submits

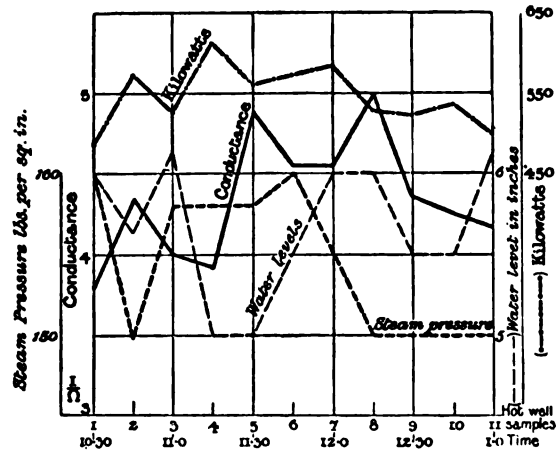

Fig. 5.

detailed results of certain of these tests. From April 25 to September 19, 1908, seven tests were taken under varying conditions. The first was on a Stirling boiler at the Shoreditch power station with a load of from 452 kw. to 616 kw., an hourly evaporation of about 15,000 lb., and pressure ranging from 150 lb. to 160 lb. The heating surface was 3,250 sq. ft., and the height of water in the gauge glass was from 5 in. to 6½ in. As was the case in all the other tests, hot-well samples were taken every quarter of an hour, whilst an average sample of the boiler water was secured by a slow uninterrupted trickle from

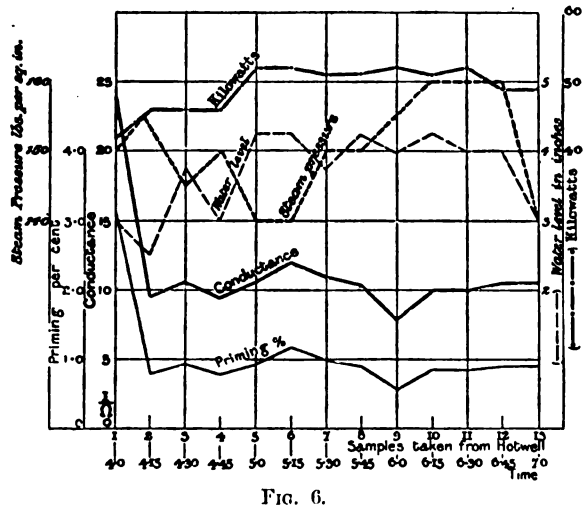

Fig. 6.

the gauge cock. The variation in specific conductance of the hot-well samples was very small, the minimum being 3·75 reciprocal megohms and the maximum 5·0 reciprocal megohms. The boiler water was unusually free from saline matter. Its specific conductance, which was 42·5 reciprocal megohms at 13°C., indicates that it contained only from 25 to 30 parts per million of dissolved solids. Fig. 5 shows the conditions and results of this test. A three hours' test taken on another Stirling boiler showed that the boiler water was of an exceptional

Digitized by Google

degree of purity, and contained probably not more than 10 parts per million of saline matter. The author does not give curves for percentage of priming in these Shoreditch tests owing to the discovery of defects in the tubes, but it is manifest, from the very low conductance of the hot-well samples, that the priming must have been very slight—probably not greater than 0·1 per cent. in the first test, and not much above this figure in the second test.

The next test, at the Epsom power station, on July 15th, was on a dry-back boiler of the Davey-Paxman economic type, and extended over three hours with an hourly evaporation of from

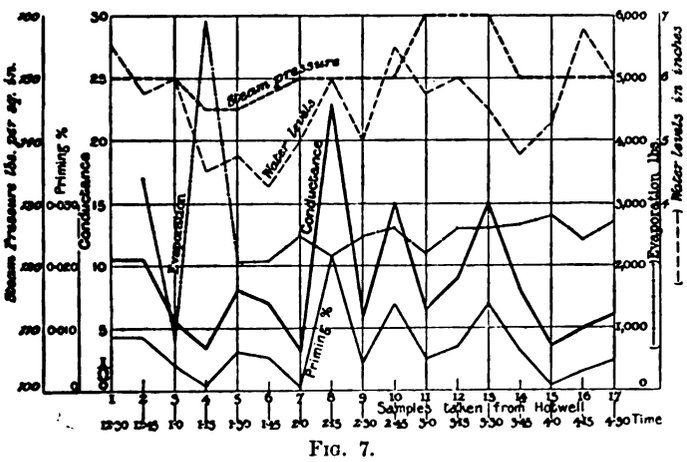

FIG. 7.

1,048 lb. to 1,185 lb. of water; a steam pressure of 140 lb. to 160 lb.; heating surface, 1,180 sq. ft.; height of water in gauge glass, 3 in. to 4¼ in., and a load of from 42 kw. to 52 kw. In this case the boiler water was of a totally different character from that at the Shoreditch station. Its specific conductance was 680 reciprocal megohms at 20°C., representing a proportion of dissolved solids amounting to several thousand parts per million. The hot-well samples varied in specific conductance from 8 to 24·5 reciprocal megohms; but the highest figure was not nearly approached in any other than the first sample taken, and may be ascribed to insufficient washing out of the interior of the pipes before beginning the collection of the samples. The corresponding amounts of priming vary from 0·6 to 3·0 per cent. The curves for this test are given in Fig. 6.

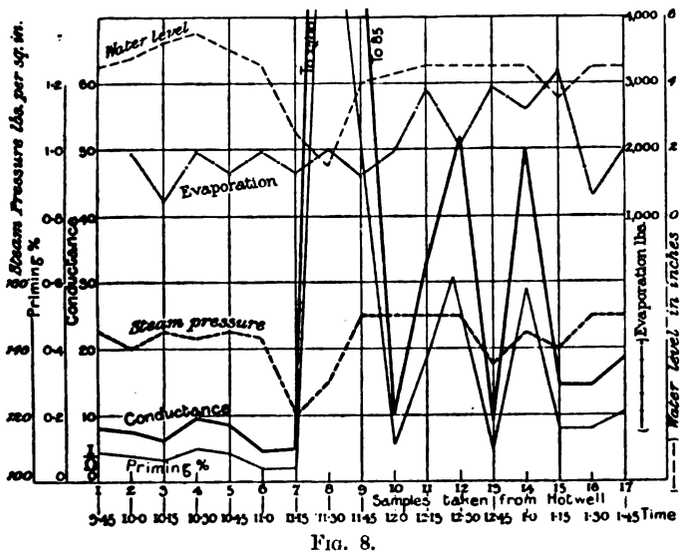

FIG. 8.

Particulars of a test taken at Kelham Island power station, Sheffield, on four Stirling boilers, are next given by the author. The first two of these boilers were of the marine type, the others were five-drum boilers. The boiler water from the former had a specific conductance of 66 reciprocal megohms, and that from the latter 870 reciprocal megohms at 26·5°C.; whilst the hot-well samples varied from 3·32 to 10·77 reciprocal megohms. The corresponding percentages of priming range from 0·06 to 1·24. As was the case at Epsom, the highest figure was obtained from the first sample only, and the same remarks apply.

Southend power station was selected for the next test, when the samples were collected during four hours. A Babcock & Wilcox boiler, with a heating surface of 2,900 sq. ft., and a water level of 4¼ in. to 6¾ in., was evaporating from 9,526 lb. to 10,940 lb. of water per hour at pressures of 140 lb. to 160 lb., with a load which varied considerably. The boiler water was strongly alkaline, and its specific conductance at 17°C. was approximately 91,240 reciprocal megohms. The hot-well samples had a specific conductance of from 3 to 23 reciprocal megohms at 16°C., indicating priming not exceeding 0·022 per cent. Fig. 7 gives details of this run.

At Southend power station a four hours' test was also begun on a Stirling boiler. After an hour and a half it was found necessary to join up a Babcock & Wilcox boiler, so that, although this run cannot be regarded as a comparative test, it shows very interesting results from the time of joining up the boilers until the end of the run (Fig. 8). The high conductance of the hot-well water when both boilers were joined up was probably due to the washing out of dirty steamways, for all the samples giving high readings were contaminated with more or less of earthy suspended matter.

The final test of this series was also taken at Southend power station on two Davey-Paxman Economic boilers, having a combined heating surface of 2,360 sq. ft., evaporating jointly from 8,736 lb. to 10,524 lb. of water per hour at a pressure of 145 lb. to 150 lb., with a very variable load. The water levels

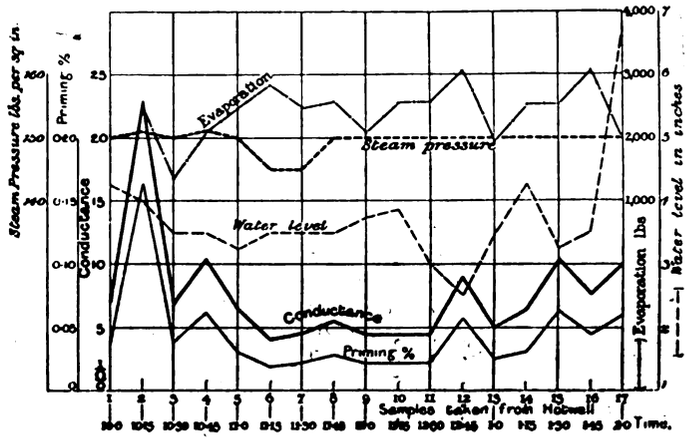

FIG. 9.

in the gauge glasses measured from 2½ in. to 7 in. The boiler water had a specific conductance of 14,910 reciprocal megohms at 18°C., whilst the hot-well samples ranged from 4·0 to 23 reciprocal megohms, and the extent of priming indicated varies from about 0·02 to 0·16 per cent. (Fig. 9).

So far as checking the operation of steam plants by conductivity methods is concerned, their application does not cease with checking the nature of the feed water or with ascertaining condenser tightness, or even with defining boiler priming. A film of oil is more to be dreaded than scale-forming impurities in the management of boilers. An oil eliminator in one form or another is a necessary adjunct in all electricity supply stations containing reciprocating sets, but their careless operation in a manner other than that designed by the makers may involve the substitution of a less evil for a greater one. The author has good reason to believe that in certain cases an excess of chemicals is added beyond that required for the elimination of the oil. This in cumulative small doses can only result in the increasing impurity of the boiler water through its enrichment with a substance which by common consent is regarded as a source of priming.

A last point may be mentioned. Where hard waters containing an excessive quantity of calcium and magnesium carbonates are softened by the Clark process, the conductivity tube and conductance meter can be used as a substitute for the standard soap test in defining how far the process of softening has been carried.

"THE ELECTRICIAN" INDUSTRIAL SUPPLEMENT.

With "THE ELECTRICIAN" for Sept. 14, 1906, was issued the first of a series of "Industrial Supplements," to be published from time to time with "THE ELECTRICIAN." The fifty-first issue of the Supplement was published (Gratis) with the last number of "THE ELECTRICIAN."

The "INDUSTRIAL SUPPLEMENT" is a comprehensive record of developments in Electrical Plant, Machinery, Apparatus, Accessories, Sundries and Materials, and of their proved suitability for various Industrial purposes.

FEED WATER TESTS.

The testing of water is one of those operations which may require a good deal of expert knowledge, the extent of such knowledge depending upon the object in view. Thus, a complete analysis, including the determination of free and albuminoid ammonia, such as may be necessary for hygienic purposes, is elaborate, and cannot be attempted except by the trained chemist. On the other hand, the determination of temporary and permanent hardness is a much simpler matter, and fortunately, in the case of the boiler user, these are the points on which information is chiefly desired. Standard soap solution is easily obtained, and its use is one of the simplest operations in quantitative work. Even the determination of total hardness by evaporation presents no difficulties to anyone who is accustomed to the use of a balance. Moreover, determinations of this kind are not often required. Initially a fairly careful examination may be desirable, but the water of a locality does not as a rule change its quality to any great extent. The amount of temporary hardness is therefore the most important quantity in every-day running, and this may require checking from time to time, more particularly in connection with water-softening plant.

In a communication to the Institution of Electrical Engineers—of which an abstract will be found elsewhere in the present issue—Mr. W. POLLARD DIGBY points out that chemical tests are not the only tests that are available in the examination of water. Electrical methods may also be applied. Thus, his tests show that as the hardness increases, the conductivity also increases proportionally. This result was obtained with water in which the hardness was due solely to calcium carbonate. Doubtless such a result would apply more or less also to water containing other impurities, provided that a given quality of water

Digitized by Google

was being considered. The difficulty, of course, is that an electrical test cannot distinguish between the different impurities. The effect on conductivity may be much the same whether the hardness is permanent or temporary, whereas it is important to be able to distinguish between the two. We think, therefore, that the electrical methods proposed by Mr. DIGBY will be more useful for the other objects that he mentions than for testing water for hardness alone.

The other uses to which we refer depend upon determining the amount of water finding its way into water of purer quality. Thus, in the case of condensed steam, the water will be of considerably lower conductivity than in the case of the circulating water. By measuring the conductivity of some condensed steam which is not passed through the condenser, and also the conductivity of the water passing from the condenser to the hot well, any alteration through the action of the condenser becomes evident. If these two figures are the same all is well, but if the conductivity of the water passing to the hot well is considerably higher than the figure obtained for condensed steam that has not passed through the condenser, it may be assumed that the effect is produced by leakage in the condenser tube. By referring to standard curves the extent of the leakage may be determined. Similarly, if the conductivity of the hot well water is low when the load on the engine is small, but increases as the load is increased, it may be inferred that the boiler is priming when giving more steam. By referring again to standard curves for the particular water in use, the percentage of priming can be found.

The apparatus used is simple, and consists of a conductivity tube with an electric generator and ohmmeter, on the lines of the familiar "Megger," but the pointer, instead of indicating megohms, indicates conductance or reciprocal ohms and megohms. In order to avoid trouble from polarisation the electrodes are tubes, and the water is made to flow through them so as to remove any polarising film.

It appears to us that such tests are distinctly useful, the more so as they afford means for determining effects, the results of which cannot be isolated easily by other methods. At the present time, when station engineers are striving to eliminate every possible inefficiency, it is well to have tests of this kind available, more particularly if, as in the present instance, they can be applied simply and without any great cost.

REVIEWS.

(Copies of the undermentioned works can be had from THE ELECTRICIAN Office, post free, on receipt of published price, adding 3d. for books published under 2s. Add 10 per cent. for abroad or for foreign books.)

Theoretical Elements of Electrical Engineering. By CHARLES PROTEUS STEINMETZ. 3rd edition. (New York: The McGraw-Hill Book Co.) Pp. ix. + 437. $4 net.

It is somewhat amusing to imagine the feelings of those who might get hold of this work under the impression derived from its title that they were about to gain a general elementary knowledge of electrical engineering. Had the author entitled it "The Theory of Electric Generators and Motors" it would have saved some shocks. With this remark, however, criticism almost ends, as the presentation of this all-important subject is so unique and complete that there is no other work to compare with it. For those who have the time and ability to read it thoroughly it will prove most valuable and suggestive, but it must be regarded as essentially of an advanced character, as the bulk of the volume presupposes a knowledge of more than half of the author's "Alternate-current Phenomena."

The present volume commences with a short introductory section on "General Theory," which is perhaps intended to justify the title, but which is hardly happily conceived. The author teaches electromagnetism in his own way by speaking of magnetomotive force in ampere turns, and magnetising force as the number of ampere turns per centimetre. This required a little adjusting when permeability is brought in, and no indication is given to the unwary that there is anything unusual about this treatment. On p. 17 the form factor of an A.C. wave is given as the ratio of the ordinary form factor to its value for a sine curve, an innovation which is perhaps to be commended. On p. 26 the author defines the time constant of a circuit as the reciprocal of the ordinarily accepted term, and although he gives reasons for this in a footnote, it does not get over the fact that his quantity is not a time. The introduction of alternate-current vectors on p. 44 follows the same procedure as in the "Alternate-current Phenomena," deriving it from the polar diagram of the wave, but this method has had the objectionable feature of reversing the sense of rotation in vector diagrams, and the advantages claimed for it over the treatment of the rotating vector as a generating crank are not convincing. It need hardly be said, however, that none of these points in any way affect the results given us.

After some general applications of the theory to transformer and transmission lines which are more or less familiar, we are introduced to Part II., entitled "Special Apparatus." Dealing first with synchronous machines the calculation of E.M.F. leaves breadth coefficients out of account, although a somewhat vague hint is given as to the necessity for considering the phases of the E.M.F.s in the separate conductors. The elimination of harmonics by fractional pitch windings is, however, clearly pointed out.

Coming next to the important question of regulation, the author introduces the term "nominal generated E.M.F. for the fictitious E.M.F. generated on the synchronous impedance theory, which will probably find general favour. The effects and similarity of armature reaction and leakage inductance are pointed out, but the essential distinction between them that the former combines with the magnetising force of the field coils, and has its effect, therefore, affected by the saturation of the poles, while the latter is independent of it is not clearly indicated. True, we find later, when dealing with short-circuits, that the effect of armature reaction on the poles is considered as being annulled by secondary currents generated in the field coils, but the absence of this from the regulation section has brought about the omission of no-load and short-circuit characteristics, and the predetermination of load characteristics by the well-known methods. But against this we have to set some very interesting and original conclusions respecting sudden short circuits, effects of teeth, &c.

The remaining subjects dealt with are direct and alternating current commutating machines, synchronous converters and induction machines. As would be expected, the treatment of alternate-current commutator motors is of great interest, and we do not remember ever seeing anything like such a simple, clear and full description of the problems to be solved and the methods of solving them.

Space forbids dealing with the remainder of the book, but enough has been said to show that Prof. Steinmetz has given us a work of considerable originality, and which will be of great value to the designer and to advanced teachers.

C. V. DRYSDALE.

Technische Schwingungslehre. By Dr. WILHELM HORT. (Berlin: Julius Springer.) M.6·40.

The author of this little work, Dr. Hort, of the Siemens-Schuckert works, has set out to give in a fairly elementary form the theory of oscillation problems as found by engineers. As a number of these oscillations depend on the simple type of linear differential equations, the beginning of the book is devoted to the theory of such equations, with examples taken from undamped galvanometer swings and loaded beams. Following

Digitized by Google

these come simple damped and forced oscillations, the practical applications being taken chiefly from electrical circuits, including a very interesting case in which the polarity of an exciter was reversed by the blowing of the fuses in the circuit of the dynamo excited by it; there are also descriptions of seismographs and vibration detectors.

The second section deals with more complex problems. After a brief exposition of Lagrange's equations and D'Alembert's principle, the author deals with the production of compound oscillations and their resolution by means of Fourier's theorem, an actual example of the latter being worked out for the crank effort diagram of a steam engine. Simple as the method is, it seems to be comparatively unknown to engineers, but with the aid of the convenient table of trigonometrical quantities given in the book, the harmonic analysis is rendered as simple as possible. The applications of these principles lead to the solutions of problems of great practical importance, although some of those considered are not strictly of an oscillatory type; for instance, the theory of the Yarrow-Schlick-Tweedy system of balancing is worked out, and it may perhaps be remarked that the whole system is ascribed to Schlick.

From an author whose work lies among electrical machinery it is natural to expect that the theory of engine governors would be fully treated, in view of the difficulties associated with parallel running of alternators, and this forms the most complete chapter in the book. The different types of governors are considered, including the "relay" type, together with the conditions under which oscillations may be set up when alternators are run in parallel. One can only regret that this chapter is not longer, as in the space devoted to it the theory is so condensed that such an important principle as that of the Hutin-Leblanc "amortisseur" is dismissed in four lines.

The remainder of the book deals with some very modern problems, such as the Schlick gyroscope apparatus for prevention of rolling in ships, and also the elementary theory of the mono-rail car as rendered stable by gyroscopes. The book is thus brought up to date, but unfortunately its completeness has to a certain extent spoilt it. Far too much has been attempted in the space available, so that in parts the matter is so condensed as to be almost obscure. But the author's idea is excellent, and an English translation considerably amplified should fill a distinct gap in text-books. At present there are too few books which illustrate the direct applications of the calculus to practical engineering problems.

F. J. DYKES.

ANALYSIS OF LEAKAGE REACTANCE.

BY J. REZELMAN.

(*Concluded from page 615.*)

Summary. The author continues his investigations into the leakage of the windings of alternating-current machines. The expression for the permeance λ_k is considerably simplified and made much more general; the expression for the slot permeance, too, is slightly modified. The leakages of many machines have been carefully analysed and the results are here given. Bar windings also are dealt with.

SEPARATION OF THE PERMEANCES.

1. *One Phase of the Three-phase Winding.*

$$\lambda_k = 0{\cdot}92\left\{\log\left(\frac{\pi \times 27{\cdot}7}{5}\right) + 1{\cdot}3 \times 3\left(0{\cdot}63 \times \log 1{\cdot}25\right)\right\} = 3{\cdot}89,$$

$p=4$; $q=3$.

whence

$$x_{s_k} = \frac{12{\cdot}5 \times 51{\cdot}5 \times 276^2}{4 \times 3 \times 10^8} \times 26 \times 3{\cdot}89 = 0{\cdot}0409 \times 26 \times 3{\cdot}89 = 4{\cdot}15\omega.$$

The table of experiments gives 41·2 volts for 10 amperes, which corresponds to a reactance $x_{s_k} = 4{\cdot}12\omega$.

$$\lambda_{s_a} = 0{\cdot}46 \times 3\left\{\log\left(\frac{2 \times 680}{210}\right) + \mathrm{A}\right\} = 1{\cdot}12 + 1{\cdot}38\mathrm{A}$$

$$\lambda_{s_c} = 0{\cdot}46 \times 3\left\{\log\left(\frac{2 \times 680}{250}\right) + \mathrm{A}\right\} = 1{\cdot}02 + 1{\cdot}38\mathrm{A}$$

whence

$$x_{s_a} = 0{\cdot}0409 \times 36\{1{\cdot}12 + 1{\cdot}38\mathrm{A}\} = 1{\cdot}65 + 2{\cdot}03\mathrm{A}$$

$$x_{s_c} = 0{\cdot}0409 \times 32\{1{\cdot}02 + 1{\cdot}38\mathrm{A}\} = 1{\cdot}33 + 1{\cdot}80\mathrm{A}$$

and $$x_{s_a} + x_{s_c} = 2{\cdot}98 + 3{\cdot}83\mathrm{A}.$$

The table of experiments gives $32{\cdot}1/10 = 3{\cdot}21\omega$, therefore $\mathrm{A} = +0{\cdot}06$. There remains

$$x_{s_n} = \frac{101{\cdot}3 - 41{\cdot}2 - 32{\cdot}1}{10} = 2{\cdot}8\omega \text{ and } \lambda_n = 2{\cdot}64.$$

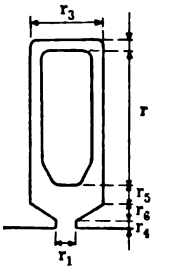

FIG. 5.

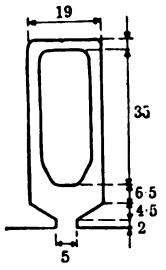

FIG. 6.

2. *Two Phases in Series.*

$$\lambda_k = 0{\cdot}92\left\{\log\left(\frac{\pi \times 27{\cdot}7}{5}\right) + 0{\cdot}8 \times 6\left(0{\cdot}68 + \log 1{\cdot}25\right)\right\} = 4{\cdot}57$$

$p=4$; $q=6$.

whence $$x_{s_k} = 0{\cdot}0818 \times 26 \times 4{\cdot}57 = 9{\cdot}72\omega.$$

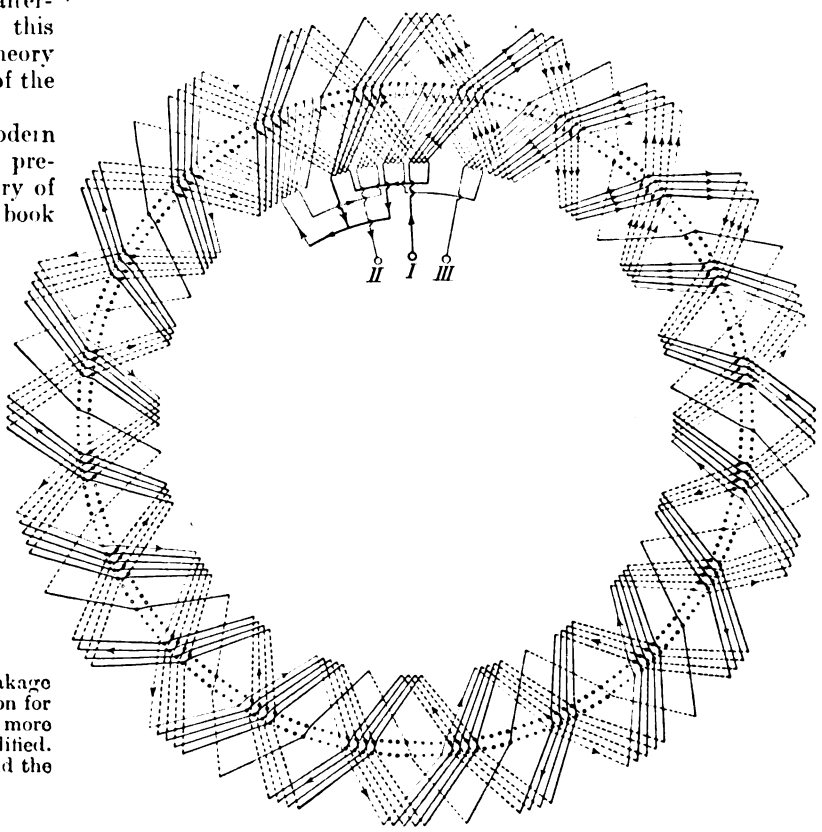

FIG. 7.—WINDING PER POLE. TWO BARS PER SLOT.
Phases I. and II. in series.

The table of experiments gives 96·8 volts for 10 amperes, whence $x_{s_k} = 9{\cdot}68\omega$.

The reactance of the coil ends is increased by

$$\frac{66{\cdot}2}{2 \times 31{\cdot}5} = 1{\cdot}05.$$

There remains

$$x_{s_n} = \frac{218 - 96{\cdot}7 - 66{\cdot}2}{10} = 5{\cdot}5\omega \quad et \quad \lambda_1 = 2{\cdot}59.$$

3. *Three-phase.*—The results are the same as in the preceding case; the mutual induction between the coil ends increases their reactance in the ratio $33{\cdot}5/31{\cdot}5 = 1{\cdot}06$.

Digitized by Google

4. *One Phase of the Two-phase Winding.*

$$\lambda_k = 0{\cdot}92\left\{\log\left(\frac{\pi \times 27{\cdot}7}{5}\right) + 6\left(0.68 + \log 1{\cdot}333\right)\right\} = 5{\cdot}57$$

$p=3$, $q=6$.

Whence

$$x_{s_k} = \frac{12{\cdot}5 \times 51{\cdot}5 \times 414^2}{3 \times 6 \times 10^8} \times 26 \times 5{\cdot}57 = 0{\cdot}0614 \times 26 \times 5{\cdot}57 = 8{\cdot}90\omega.$$

The table of experiments gives $90/10 = 9\omega$.

$$\lambda_{s_a} = \lambda_{s_b} = 0{\cdot}46 \times 3\left\{\log\left(\frac{2 \times 680}{210}\right) + A\right\} = 1{\cdot}12 + 1{\cdot}38A$$

$$\lambda_{s_c} = 0{\cdot}46 \times 6\left\{\log\left(\frac{2 \times 680}{470}\right) + A\right\} = 1{\cdot}27 + 2{\cdot}76A.$$

Whence

$$x_{s_a} + x_{s_b} = 0{\cdot}0614 \times 36(1{\cdot}12 + 1{\cdot}38A) = 2{\cdot}47 + 3{\cdot}04A$$

$$x_{s_c} = 0{\cdot}0614 \times 32(1{\cdot}27 + 2{\cdot}76A) = 2{\cdot}49 + 5{\cdot}42A.$$

and $$x_{s_a} + x_{s_b} + x_{s_c} = 4{\cdot}96 + 8{\cdot}46A.$$

The table of experiments gives $\frac{72{\cdot}5}{10} = 7{\cdot}25\omega$.

Whence $A = +0{\cdot}271$.

The second phase with the same values l_s and U_s, although bent back and nearer to the iron, has practically the same reactance.

There remains $x_{s_a} = \frac{205{\cdot}5 - 90 - 72{\cdot}5}{10} = 4{\cdot}3\omega$

and $\lambda_a = 2{\cdot}71$.

5. *Two Phases in Series.*—The results are the same as for the preceding case; the experiment proves that the mutual induction between the phases is negligible.

6. *One Coil of three Slots, a, b and c.*—The reactance x_{s_k} of this coil separately excited is greater than when it forms part of one phase connected three-phase (case 1); there is an augmentation of $\frac{2{\cdot}63}{2{\cdot}24} = 1{\cdot}175$, again due to the disappearance

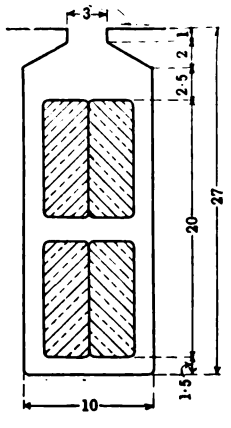

FIG. 8.

of the negative mutual induction between the coils. From the table of experiments the reactance of the end coils, calculated for four coils, is $4 \times \frac{9{\cdot}8}{10} = 3{\cdot}92\omega$, $x_{s_a} + x_{s_c} = 2{\cdot}98 + 3{\cdot}83A$, as in case 1, whence $A = +0{\cdot}245$.

For λ_a the value is still found to be 2·7.

7. *One Coil of two Slots, a and b.*

$l_s = 725$ mm.; $l_{s_a} = 375$ mm.; $U_{s_a} = 155$ mm.

$l_{s_c} = 350$ mm., $U_{s_c} = 175$ mm.

Calculated for four complete coils, we find

$$x_{s_a} + x_{s_c} = 3{\cdot}86 + 4{\cdot}08A = 5{\cdot}11\omega.$$

Whence $A = +0{\cdot}252$.

8. *One Coil of Two Slots, b and c.*

$l_s = 630$; $l_{s_a} = 350$; $U_{s_a} = 155$ mm.

$l_{s_c} = 280$; $U_{s_c} = 175$ mm.

In like manner we find

$$x_{s_a} + x_{s_c} = 3{\cdot}155 + 3{\cdot}55A = 4{\cdot}23\omega.$$

Whence $A = 0{\cdot}309$.

We see that for the coil excited separately (cases 6, 7 and 8), the value of A is about the same as for a winding per pole (cases 4 and 5), whilst it approaches zero for a winding per consequent poles (cases 1, 2 and 3).

This proves that it is, in reality, necessary to differentiate between the winding per pole and that per consequent poles.

By applying the above to several machines the following results have been obtained:—

Winding per pole.				Winding per consequent poles.			
H.P.	p	A	R = x_s measured / x_s calc. (A = 0)	H.P.	p	A	R = x^s measured / x_s calc. (A = 0)
48	1	+0·278	1·32	2,000	2	+0·065	1·08
220	1	+0·360	1·45	5,000	2	+0·05	1·05
220	1	+0·355	1·44	4,500	2	−0·05	0·94
350	7	+0·25	1·32	350	4	+0·065	1·09
175	3	+0·271	1·46	100	4	−0·03	0·96
175	3	+0·245	1·315	175	4	+0·06	1·08
175	3	+0·252	1·33				
175	3	+0·309	1·35				
175	4	+0·420	1·53				

1. *Winding per Pole.*
   A varies between +0·25 and +0·40, mean value: +0·30.
   R varies between +1·30 and +1·50, mean value: +1·4.

2. *Winding per Consequent poles.*
   A varies between −0·05 and +0·07, mean value: +0·03.
   R varies between −0·94 and +1·08, mean value: +1·03.

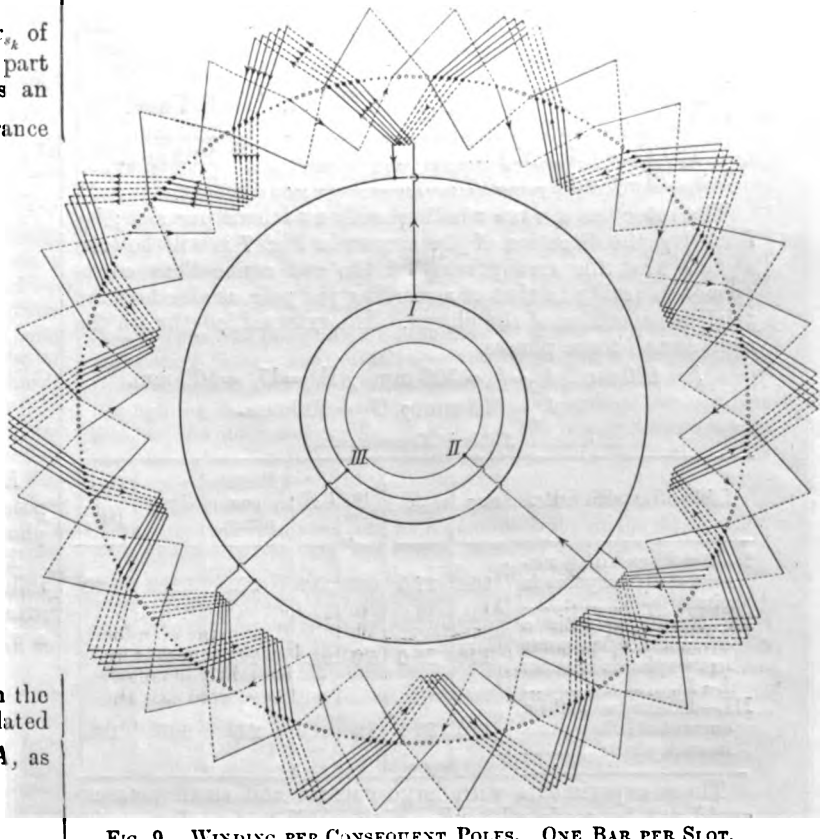

FIG. 9.—WINDING PER CONSEQUENT POLES. ONE BAR PER SLOT.
Phases I. and II. in series.

Eight machines with windings per pole, examined by the new formulæ, give an augmentation of the reactance of the coil ends, due to mutual induction, varying between 1·25 and 1·5, mean value 1·35.

For a winding per consequent poles this mutual induction is negligible.

3. *Permeance* λ_a.

It remains for us to analyse the permeance λ_a; we have written

$$\lambda_a = 1{\cdot}25\left(\frac{r}{3r_3} + \frac{r_5}{r_3} + \frac{2r_6}{r_1 + r_3} + \frac{r_4}{r_1}\right) \text{(Fig. 5)},$$

Digitized by Google

but experience shows that the formula gives too small values. The error must be attributed to the two last terms, which must be rectified if we wish to take account of the exact importance of each part.

In tracing out the scheme of the lines of force, it is found that the permeance of the "slit" depends on $\frac{r_5}{r_1}$ and on $\frac{r_1}{r_4}$, so as to take the form $\frac{r_4}{r_1}\left\{1{\cdot}5+0{\cdot}015\left(\frac{r_1}{r_4}\right)^2\right\}=1{\cdot}5\frac{r_4}{r_1}+0\,015\frac{r_1}{r_4}$.

The third term can be made to agree more closely with the actual value by dividing the height r_6 into three equal parts; for simplicity we will divide it into two parts, $\frac{1}{3}$ from the bottom, near to the slit, and $\frac{2}{3}$ above. This term then becomes

$$\frac{2r_6}{5r_1+r_3}+\frac{2r_6}{r_1+2r_3}.$$

From the results of experiments, the curvature of the lines of force near to the slit is found to be so important for high voltage machines with large r_3 and r_6, that it is even necessary to take

$$\frac{3r_6}{5r_1+r_3}+\frac{2r_6}{r_1+r_3}.$$

The complete formula then becomes

$$\lambda_a=1\,25\left(\frac{r_2}{3r_3}+\frac{r_5}{r_3}+\frac{3r_6}{5r_1+r_3}+\frac{2r_6}{r_1+2r_3}+1{\cdot}5\frac{r_4}{r_1}+0\,015\frac{r_1}{r_4}\right).$$

Applied to the motor we have been considering we find (Fig. 6)

$$\lambda_a=1\,25\left(\frac{35}{37}+\frac{6{\cdot}5}{19}+\frac{3\times4{\cdot}5}{5\cdot5+19}+\frac{2\times4{\cdot}5}{5+2\times59}+1{\cdot}5\times\frac{2}{5}+0{\cdot}015\times\frac{5}{2}\right)$$
$$=2{\cdot}64.$$

Bar Windings.

Rotor of the three-phase 175 h.p. Asynchronous Motors, 4 poles, 50 periods, 750 revs. per min.

Dimensions.

$\phi_i=747$ mm.	$\tau=294$ mm.
$l=270-3\times7{\cdot}5$ mm.....	$l_i=260$ mm.
120 slots (10×27)	$t_1=19{\cdot}5$ mm.
S_a...$2-p=4$	$q=5$.

The rotor has a wave winding with two bars per slot; by following the direction of the arrows in Fig. 7 it will be seen at once that the arrangement of the end connections corresponds in reality to that of a winding per pole, as also does the relative deposition of the phases. The external lengths are the same for all three phases.

$l_a=420$ mm., $l_{a_a}=l_{a_b}=300$ mm.; $U_{a_a}=U_{a_b}=100$ mm.
$l_{a_c}=120$ mm.; $U_{a_c}=200$ mm.

Table of Experiments.

Table of experiments.	$e_{0-I.}$	$e_{I.-III.}$	e_k red.	c	Watts per phase.	Cos ϕ	$\frac{W}{I^2R_1}$
I.—Readings with a current of 100 amperes in phase 0—I.....	14·1	17·6	6·85	51·5	270	0·191	1·69
II.—Readings with a current of 100 amperes in two phases in series I.—II.....	17·6	35·0	8·5	51·5	245	0·139	1·57
III.—Readings with a current of 100 amperes in each phase	17·7	30·6	8·6	51·5	230	0·13	1·45

These experiments with large current and small pressure could not be made without an intermediate transformer for raising the voltage to a value suitable for the alternator; so the high harmonics falsify the results by giving too high voltages, especially for single phase.

Separation of the Voltages.

1. *Single Phase per Phase.*—The rotor slots are shown in Fig. 8.

$$\lambda_a=1{\cdot}25\left(\frac{20}{30}+\frac{2{\cdot}5}{10}+\frac{3\times2}{5\times3+10}+\frac{2\times2}{3+2\times10}+1{\cdot}5\times\frac{1}{3}+0{\cdot}015\times\frac{3}{1}\right)=2{\cdot}34.$$

Whence

$$\lambda_{a_a}=\frac{12{\cdot}5\times51{\cdot}5\times40^2}{4\times5\times10^5}\times26\times2{\cdot}34=0{\cdot}000515\times26\times2{\cdot}84$$
$$=0{\cdot}0314\omega.$$

The reactance $x_{a_k}=0\,0685\omega$ was determined by means of auxiliary coils, then $\lambda_k=5{\cdot}12$. Calculation gives

$$\lambda_k=0{\cdot}92\left\{\log\left(\frac{\pi\times16{\cdot}5}{3}\right)+1{\cdot}3\times5(0{\cdot}68+\log B)\right\}$$
$$=5{\cdot}2+5{\cdot}98\log B,$$

$p=4$, $q=5$.

whence B = 0.97.

From this experiment the permeance for a convex polar are seems to diminish less rapidly than the term $p/(p+1)$.

There remains for the end connections

$$\frac{13{\cdot}85-6{\cdot}85-3{\cdot}14}{100}=0{\cdot}0386\omega,$$

$$\lambda_{a_a}=\lambda_{a_b}=0{\cdot}46\times5\left(\log\frac{2\times420}{100}+A\right)=2{\cdot}12+2\,3A,$$

$$\lambda_{a_c}=0{\cdot}46\times5\left(\log\frac{2\times420}{200}+A\right)=1{\cdot}43+2{\cdot}3A,$$

$$x_{a_a}+x_{a_b}=0{\cdot}0002575\times30(2\,12+2{\cdot}3A)=0{\cdot}0164+0\,01775A,$$
$$x_{a_c}=0{\cdot}000515\times12(1{\cdot}43+2{\cdot}3A)=0{\cdot}0088+0{\cdot}0142A,$$
$$x_{a_a}+x_{a_b}+x_{a_c}=0\,0252+0{\cdot}03195A=0\,0386.$$

Whence $A=0{\cdot}42$ and $R=1{\cdot}53$.

2. *Single Phase, Two Phases in Series.*—The reactance x_{a_a} is still $0\,0314\omega$; the experiment gives $x_{a_k}=8{\cdot}5/100=0{\cdot}085\omega$. Whence $\lambda_k=6{\cdot}35$.

$$\lambda_k=0\,92\{1{\cdot}24+0{\cdot}8\times10(0{\cdot}68+\log B)\}=6{\cdot}15+7{\cdot}35\log B.$$

$p=4$, $q=10$.

We thus find for B a value even greater than unity.

There remains for the end connections $0{\cdot}175-0{\cdot}0314-0\,085=0{\cdot}0586\omega$; there is thus an augmentation of $0\,0586/0{\cdot}0386=1{\cdot}52$ by mutual induction.

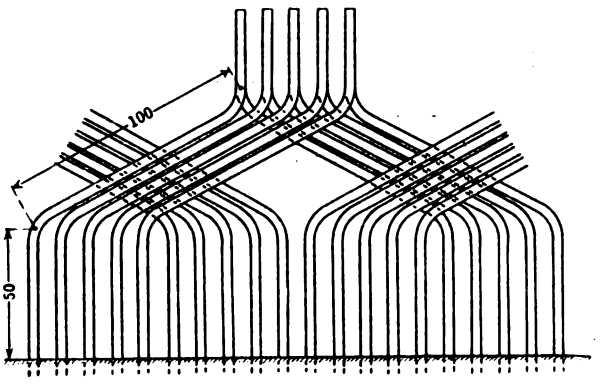

Fig. 10.—One Bar per Slot.

Rotor of a Three-phase Asynchronous 175 h.p. Motor, 20 poles, 50 periods, 800 revs. per min., 5 slots per pole and phase.

This rotor has a ware winding with one bar per slot; by following the arrows in Fig. 9 it can be seen at once that the arrangement of the end coils corresponds in reality to that of a winding per consequent poles, as also does the relative posi-

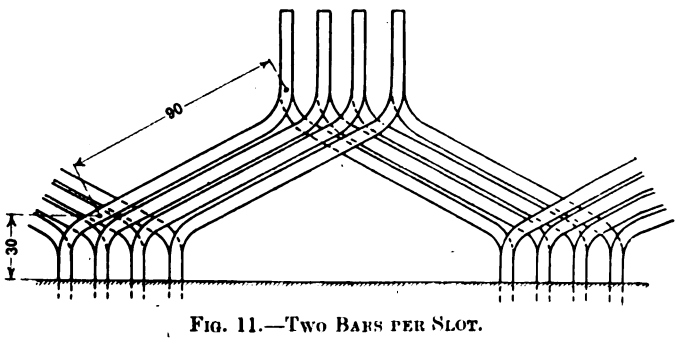

Fig. 11.—Two Bars per Slot.

tions of the phases. The sole difference is that the end connections on one side are not facing those on the other. Fig. 10 shows their arrangement exterior to the core.

Fig. 11 relates to the stator of this motor with four slots per pole and phase and two bars per slot, which therefore really forms a winding per pole.

Digitized by Google

LIBRARY OF THE UNIVERSITY OF CALIFORNIA

Resumé.—The reactance of the stator of an alternating current machine can be calculated by considering the three permeances, λ_a, λ_b and λ_c.

1. $\lambda_a = 1{\cdot}25\left(\frac{r}{3r_3}+\frac{r_3}{r_3}+\frac{3r_3}{5r_1+r_3}+\frac{2r_3}{r_1+2r_3}+1{\cdot}5\frac{r_1}{r_1}+0{\cdot}015\frac{r_1}{r_1}\right)$.

2. For a winding:

$q=\frac{1}{2}Q\ldots\lambda_c=0{\cdot}92\left\{\log\left(\frac{\pi z_1}{r_1}\right)+q\left(0{\cdot}68+\log\left(\frac{p+1}{p}\right)\right)\right\}$

$q=\ \ Q\ldots\lambda_c=0{\cdot}92\left\{\log\left(\frac{\pi z_1}{r_1}\right)+0{\cdot}5q\left(0{\cdot}68+\log\left(\frac{p+1}{p}\right)\right)\right\}$

$q=\frac{1}{3}Q\ldots\lambda_c=0{\cdot}92\left\{\log\left(\frac{\pi z_1}{r_1}\right)+1{\cdot}3q\left(0{\cdot}68+\log\left(\frac{p+1}{p}\right)\right)\right\}$

$q=\frac{2}{3}Q\ldots\lambda_c=0{\cdot}92\left\{\log\left(\frac{\pi z_1}{r_1}\right)+0{\cdot}8q\left(0{\cdot}68+\log\left(\frac{p+1}{p}\right)\right)\right\}$

3. For a winding per consequent poles, $\lambda_c=0{\cdot}46q_c\left(\log\frac{2l_c}{U_c}\right)$

in which λ_c must be divided into two parts a and c; the mutual induction between phases is negligible.

For a winding per pole $\lambda_c=0{\cdot}46q_c\left(\log\frac{2l_c}{U_c}+A\right)$ where l_c must be divided into three parts, a, b and c ($a=b$ for a winding in which q is an even number); A varies between 0·25, and 0·40; as an average value A = 0·3.

It may also be written $\lambda_c=0{\cdot}46q_c\times R\left(\log\frac{2l_c}{U_c}\right)$ where R varies between 1·3 and 1·5, in the mean R = 1·4.

For the winding per pole the mutual induction between phases augments the reactance of the coil ends by 1·25 to 1·5, an average of 1·35.

THE BEARING OF REFLECTION ON ILLUMINATION.*

BY A. S. MCALLISTER.

Summary.—The author describes a simple arithmetical method for taking into account the effect of reflections between surfaces and ascertaining the distribution of the light flux.

One of the problems connected with illumination which has usually been considered too complicated to admit of simple calculation is that dealing with the reflections and inter-reflections from and between the ceiling, floor and walls of a room. In practical illuminating engineering work the problem has been looked upon as being so complicated that use has been made of some approximate solution based largely upon the knowledge of results obtained previously under similar conditions.

The simple method here suggested has as its foundation on the absorption-of-light method of calculating illumination. According to this method, the lighting units in a room must produce the sum of the lumens absorbed by the various surfaces, the lumens absorbed by each surface being determined as the product of the area of the surface in square feet, the incident illumination density in candle-feet and the absorption coefficient. The method gives no clue as to the distribution of illumination over each surface, but takes fully into account all the inter-reflections between the various surfaces, and permits one to ascertain the total amount of light which the lamps must supply directly to each surface involved.

Thus, let us consider first the relations in an extremely narrow, long hall of great height, against one wall of which a total light of, say, 2,000 lumens (160 mean spherical candles) is sent directly from the lamps, the other wall being illuminated exclusively by the light reflected from the former wall; assume that the light-absorption coefficient for each wall is 0·20. The problem is to determine the total incident flux on each wall and the amount absorbed by each. Assign arbitrarily a value of 100 units to the total light incident upon the first wall. Eighty per cent., or 80 units, of this light are reflected to the other wall, where 20 per cent., or 16 units, are absorbed, 64 units being returned to the first wall. Thus, of the 100 units reaching the first wall 64 are reflected from the second wall and 36 come directly from the light sources. The 36 units of light are equal to 2,000 lumens, so that each unit has a value of 55·55 lumens. It is seen, therefore, that on the first wall the incident lumens have a value of 5,555, of which 2,000 come directly from the lamps and 3,555 are reflected from the second wall. The second wall receives $5{,}555\times0{\cdot}80=4{,}444$ lumens, and reflects $4{,}444\times0{\cdot}80=3{,}555$ lumens to the first wall. The former wall absorbs $5{,}555\times0{\cdot}20=1{,}111$ lumens, and the latter $4{,}444\times0{\cdot}20=888$ lumens, the total being the 2,000 lumens produced by the lamps. The calculations show that, quite independent of the wall upon which the light falls directly from the lamps, the illumination upon one wall cannot differ from that upon the other by more than 20 per cent. when the light-absorption coefficient has a value of 0·20.

Taking next the case where one wall has an absorption coefficient of 0·10 and the other a coefficient of 0·50, the author shows that, quite independent of the wall upon which the 2,000 lumens from the lamp fall directly, that wall receives an incident flux of 3,636 lumens, while the other wall receives a value less than this amount by the light absorbed by that wall upon which the rays from the lamp are directed. With the rays directed toward the wall having a low absorption coefficient the other wall received 3,272 lumens, while with the rays in the opposite direction the indirectly lighted wall received 1,818 lumens. It is evident from the above that reflection may play a highly important part in illumination, and that the direction of the light from lamps becomes of less and less importance as the coefficient of absorption decreases. The absorption-of-light method of calculation thus affords a valuable insight into the limitations upon the distribution of illumination between inter-reflecting surfaces, and represents a convenient simple method for solving certain of the problems in illumination usually considered complex.

It is interesting to apply this method to the determination of the exact amount of flux which the lighting units must direct toward each of two inter-reflecting surfaces illuminated to different light densities and having different absorption coefficients. Assume that in a room 10 ft. wide by 15 ft. long, having a ceiling absorption coefficient of 0·20 and a floor coefficient of 0·90, the incident ceiling illumination is to be 1 candle-ft. and the incident floor illumination 3 candle-ft. Neglect the reflection to and from the walls from and to the ceiling and floor, or rather assume that the light received by the walls from the ceiling and floor is equal to that reflected from the walls to the other surfaces. The total incident ceiling illumination will be $15\times10\times1=150$ lumens, of which $150\times0{\cdot}20=30$ are absorbed and 120 are reflected to the floor. The incident illumination on the floor will be $15\times10\times3=450$ lumens, of which 405 are absorbed and 45 are reflected to the ceiling. Of the flux of 150 lumens on the ceiling 45 come from the floor, so that the lamps must supply 105 lumens. Similarly, the lamps must supply $450-120=330$ to the floor. The ceiling receives directly from the lamps 105 lumens and absorbs only 30 lumens, while the floor receives 330 lumens from the lamps directly and absorbs 405. It will be seen that the total lumens absorbed are 435, and this total is equal to the sum of the fluxes sent to the surfaces from the lamps, but there is no immediate relation between the lumens directed toward each surface from the lamps and the lumens absorbed by that surface. Thus, the lamps send 330 lumens to the floor; which absorbs 405 lumens from a total of 450 received by it. It is noteworthy in this connection that the familiar point-by-point method applied to the lighting installation here assumed would indicate an incident flux on the floor and ceiling of 330 and 105 respectively, whereas the true values are 450 and 150, the increase being due solely to the inter-reflection between the two surfaces.

An objection which may be urged against the absorption-of-light method is that it ignores any lack of uniformity in the distribution of illumination over the individual surfaces considered. Such a criticism is fully justified by the facts, but it has no bearing on the value of the method both as a check on other methods which take into account the variation of light distribution and as a direct final method to be used in problems where the variation in light density is of no importance. For solving problems connected with the illuminating of reflecting surfaces, investigating quantitatively the effect of inter-reflection between surfaces and ascertaining the limits in the distribution of light flux between illuminated surfaces, the absorption-of-light method should prove of much value to the illuminating engineer.

* Abstract of an article in the "Electrical World."

TRACKLESS TROLLEY SYSTEMS ON THE CONTINENT.

In the autumn of last year the Bradford Corporation decided to appoint a committee to visit the various trackless trolley systems employed on the Continent, with a view to examining into their special features and to discovering whether any of them would be suitable for use in Bradford.

The committee left this country on November 27th last, and inspected a number of systems in use on the Continent, as well as a number of tramways worked in the ordinary way. They have now issued their report, which deals at considerable length with both these subjects.

After describing the Berlin and Vienna tramways, the report goes

Digitized by Google

on to deal with the Mercedes-Stoll system used on the trackless trolley cars, on the outskirts of the latter city. In this system, it will be remembered, the overhead equipment is similar to that of an ordinary tramway, with the exception that the wires are supported in such a manner that the trolley bogie, which is simply a four-wheel trolley, runs along the wires similar to a bogie running on an ordinary railway track. This is electrically connected to the vehicle by means of an insulated cable terminating on a spring drum, which is so designed that the slack of the wire is automatically taken up, or additional cable paid out, according to the circumstances of the case. The driving arrangements on the platform are similar to those of an electric car. The motors on this particular system are gearless, and are contained in the hub of the rear wheels. The vehicle is rubber-tyred and has a seating capacity of from 12 to 15 persons, and runs along the road very smoothly and practically without noise. Due to the flexibility of the trolley arrangement, it is almost as free in its use of the road as a self-propelled type of vehicle.

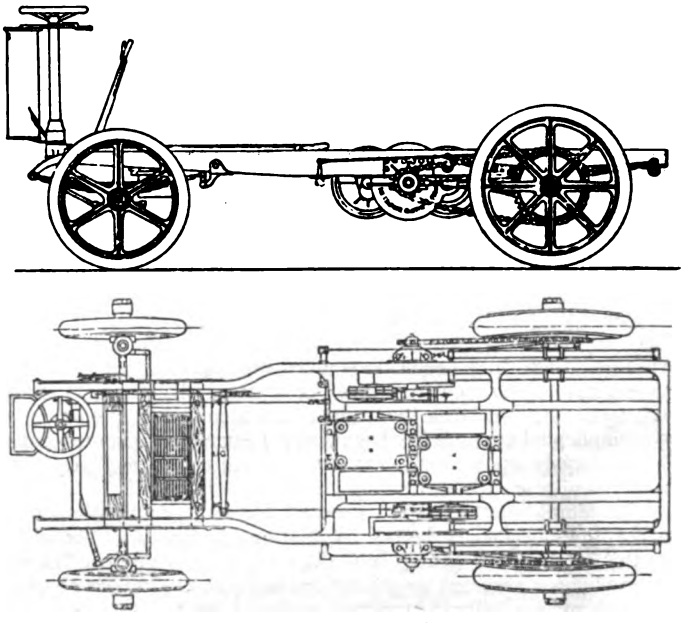
The steepest gradient on the route inspected by the deputation is 1 in 12, and the surface of the roadway being fairly good, the vehicles have no difficulty in negotiating it. The running speed of the vehicle is fairly high and comparable with that of an ordinary tramcar. The running cost of these vehicles in Vienna is very low, namely, 4·52d. per bus-mile. This is, however, with a driver only the entrance and exit to the vehicle being at the driver's end, thereby dispensing with the services of a conductor. The deputation were informed that the overhead equipment on this particular route cost from £700 to £800 per mile, but that was with the use of wooden poles, and the equipment generally was of a cheaper construction than what is usual in this country. The deputation estimate that in England the overhead equipment for railless electric traction would cost roughly from £1,200 to £1,500 per mile, thus showing a considerable saving on capital account, and hence in standing charges, over an ordinary tramway system costing, inclusive of permanent way, £13,000 to £15,000 per route-mile. This consequently renders the railless trolley system an almost ideal method for the testing of proposed routes for traffic purposes, and for the serving of districts where the population is so meagre that the laying of permanent way and the instituting of an ordinary tramway service is entirely out of the question. The roadway is of the ordinary macadamised type and similar to the high roads in this country. The deputation are of opinion that the wear and tear of the roadway, as a result of this traffic, is not in excess of that occasioned by ordinary road vehicles of similar size and weight; in fact, the use of rubber in place of iron tyres, which are mostly used by other vehicles of similar weight, should occasion less road wear. So far as the deputation can at present see, a vehicle suitable for English conditions, carrying about 20 passengers, with a driver and a conductor, could be operated on average roads in the Bradford district at about the same running cost per car-mile as an ordinary 60 passenger tramcar, viz., 7·25d. The Vienna Tramways Department have experimented largely with petrol-driven vehicles in competition with this system, but the high cost of maintenance of a petrol engine, coupled with the noise and smell, caused it to be very much out-distanced by the railless trolley vehicle.

A further system of railless trolley belonging to a company near the small village of Klostermenberg, about 20 miles from Vienna, was then inspected. This system differs from the one previously mentioned, in that only two trolley wires in place of four are used. The vehicles are similar to those in use in Vienna, but when two vehicles desire to pass it is necessary for drivers to bring their respective car platforms together and change trolleys from one car to the other.

At Milan the deputation inspected the "Filovia" system, which is in use in several parts of Italy. The route extends from Argegno to St. Fedele, which is on the summit of a range of mountains. The road is of the ordinary macadam type, but, due presumably to the steep gradient and curves, is not in a very good state of repair. It contains several very sharp "hairpin" turns, some of which are so stiff that notwithstanding the short wheel-base of the vehicle the driver found it necessary to proceed part way round the curve, reverse, and manœuvre in that way in many places where the gradient was in the neighbourhood of 1 in 8 or 1 in 9. The rise from Argegno, which is 656 ft. above sea level, is continuous up to St. Fedele, which is 2,582 ft. above sea level. The distance between the two places is a little under 5·5 miles, the average rise is therefore about 6 per cent. or 1 in 16·5, and reaches at places nearly 13 per cent. or 1 in 7·7.

The overhead line is composed of two trolley wires 9 mm. in diameter suspended in the usual way, and supported by wooden and steel poles. Unlike the Vienna system, only two wires are in use—a negative and a positive—these serving for the up and down cars. The line is fed with continuous current at a pressure of 600 volts by an overhead feeder carried by the same pole that supports the trolley wires. The car shed, which is situated at the summit of the line, is large enough to accommodate 12 cars, but at the present time the company has only four passenger cars and one goods wagon. The chassis, a diagram of one of which is shown herewith, are of the standard "Filovia" design, and are equipped with two 12 H.P. motors arranged for running in series or parallel.

The wheel-base on these cars has been kept shorter than usual (only 9 ft.) on account of the sharp curves, some of which have a radius of less than 20 ft. (The sharpest curve on the tramway system in Bradford is 40 ft.) The road wheels of the cars are fitted with single solid rubber tyres both front and back. The drive from the motor to the wheel is by means of sprocket wheel and chain, similar to the drive on a petrol motor omnibus without differential. Efficient brakes are fitted to the vehicle of both mechanical and electrical designs. The down trips on this route are always performed without utilising any electrical energy, with the exception of starting at the terminus. The cars are of the single-deck type, with seating capacity for 18 to 20 passengers, and accommodation for luggage on the roof. The weight of the cars when empty is 3½ tons. The deputation were informed that since the line was opened to the public there had been no serious interruptions, and if this is so it is a remarkable record, considering the very difficult character of the road. The railless system of traction which is being developed in Italy under the name of "Filovia" by the Società Trazione Elettrica of Milan has been found to be of considerable utility to the public. The first line of this system was laid from Pescara to Castellmare. This was constructed in 1904, and since that date a number of lines have been put in, totalling well over 50 miles in different parts of the



PLAN AND ELEVATION OF "FILOVIA" MOTOR CHASSIS.

country, all of which are in regular daily use. As a proof of the non-experimental character and stability of the railless trolley system in Italy it is interesting to know that the Italian Government have decided to grant a subsidy of £60 a year for each mile of line equipped on the railless system in districts not provided with railway or tramway service.

The trolley and current-collecting apparatus is different from that in use in the "Mercedes-Stoll" system. Instead of the four-wheel trolley bogie running on the upper-side of the wire these vehicles are equipped with an ordinary trolley pole with a specially designed head running on both wires, very similar in construction and operation to the trolley poles in use on the cars in Bradford. The mobility of the vehicle with the length of trolley-pole as in use on the Argegno line allows the car to travel on any portion of the 14 ft. of roadway, *i.e.*, 7 ft. on either side of the trolley wire. The vehicle may be stopped and turned completely round without any attention being paid to the trolley pole, the trolley taking its natural position according to the direction in which the car is travelling.

From figures supplied it appears that the energy consumed per ton-mile is about the same as that consumed on a tramcar. This is somewhat surprising, as one might expect the tractive effort of rubber tyres on an ordinary roadway to be much in excess of that of a tramway rail. The explanation, however, is probably to be found in the fact that more modern motors, of greater efficiency than the old type of tramway motor, are in use, and to the use of rubber

Digitized by Google

tyres; in addition the freedom of each driven wheel to take its own course when rounding curves is a very excellent electrical differential. The steering and control of the car is quite as good, if not better, than the control of an ordinary petrol vehicle of similar dimensions.

The deputation are indebted to Herr Webber, the general manager of the Electric Tramways Company of Spezzia, who is working a railless trolley line on the "Filovia" system from Spezzia to Fezzana, for the following figures extracted from the tramway company's accounts :—

	Pence per car-mile.
Cost of energy	0·41
General expenses	0·59
Rubber tyres	2·16
Wages—Drivers and conductors	1·40
Renewals of vehicles and line (depreciation, &c.)	0·62
Repairs to vehicles	0·46
	5·64

The circumstances of the inauguration of the installation at Mülhausen are somewhat peculiar. The tramways of Mülhausen are company-owned and operated. Some years ago the municipality requested the company to run a line out to the Zoological Gardens—a pleasure resort about 1½ miles from the centre of the town. This, however, the company declined to do on the ground that the proposed route, in their opinion, would not pay. The Corporation, therefore, installed a system of railless traction municipally operated and managed. The vehicles are of somewhat peculiar design, being fitted with iron shod wheels, the motor being attached to the front wheels and forming part of the steering bogie. The trolley-pole is similar to the Italian system. The system seems to have proved itself of great utility to the Mülhausen Corporation, and residents are provided with a way out of what was, apparently, a deadlock, insomuch that an efficient means of transit was obtained to a point where possibly a tramway line would not have paid. The gradients on the road are very heavy, but the deputation were informed that no damage had been done to the roads, beyond what one would expect with an ordinary vehicle of similar weight and dimensions.

In conclusion, the deputation are of opinion that the railless trolley systems as seen in Vienna and in Italy are such that either system could be adapted to English conditions and prove of great value to tramway authorities and to the public, in providing a means of transit to districts where the heavy capital cost would prohibit the construction of an ordinary tramway.

CORRESPONDENCE.

THE CRADLE DYNAMOMETER.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Referring to the interesting article by Messrs. Davies and Shaw on the application of the cradle dynamometer, published in your issue of the 8th inst., and to the letter of Dr. C. V. Drysdale on the same subject, I beg to point out that since the year 1902 the Laboratorio di Elettrotecnica del R. Istituto Tecnico Superiore has possessed a cradle dynamometer with knife edge suspension, designed by myself, which gives very satisfactory results.

A brief illustrated description of the apparatus appeared, on May 1, 1903, in "Engineering," on the occasion of the visit to Italy of the Institution of Electrical Engineers. From it you may see that the suspension is a knife-edge articulated parallelogram, like the one which, with a different arrangement, has been used by Dr. Drysdale.

To confirm Dr. Drysdale's statements, I may mention that ball bearings were rejected by me *a priori* for lack of sensibility, while during the past eight years it has only once been necessary to overhaul the knives of the suspension. As to the position of the machine to be tested, I would point out that, in order not to overlook the windage losses, it is convenient to place the machine to be tested upon the swinging frame when the machine is a motor, and to place the machine to one side when it is a generator, in accordance with the disposition at the Northampton Institute. Doubtless, to centre the machine upon the swinging frame requires some care and takes some time; therefore, Dr. Drysdale's disposition is preferable for ordinary measurements.

I am sending you separately a Paper on my dynamometer, and I shall be glad if you will publish my letter in your much esteemed journal.—I am, &c.,

Milan, July 20. ING. ANGELO BARBAGELATA.

FISCAL POLICY AND THE ELECTRICAL INDUSTRY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Mr. Hookham does not attempt to justify his "Imports pay for Exports" theory, but retires again behind his comprehensive challenge. To deal with this challenge adequately would require much more space than one could ask from a technical journal, while on the other hand (as one of your correspondents pointed out) "nut-shell arguments" are never complete. As I prefer to err on the side of brevity, I would submit the following lines of argument to Mr. Hookham as giving a first approximation to the truth.

(A) *Home Consumption* :—

1. Any rise in price due to Protection gives a bigger margin for the producer.
2. The consumer is in general also a producer, whether as capitalist, overseer or artisan.
3. While an individual loses as a consumer, he gains as a producer, and his purchasing power is not decreased, but probably slightly increased. (Example, wages and average prices in U.S.A.)
4. Home consumption will not go down.

(B) *Export* :—

1. Mr. Hookham says that under Protection the manufacturers will make a profit.
2. A paying industry can go in for development and can raise capital for subsidiary companies.
3. Foreign trade of recent years has depended more on enterprise and commercial development than on price. (Example, German trade with S. Africa, India and China.)
4. Even without Colonial preference our exports need not decrease, but rather the reverse.

(C) *Employment* :—

Assuming that the Home and Foreign demands remain the same, employment under Protection is obviously increased directly by the labour value of the "ready-made" goods excluded, and indirectly by the more rapid development of a dividend-paying industry.

If Mr. Hookham still objects that there must be imports to "pay" for exports, I would remind him that scientific Tariffs are not directed against foreign material, but foreign labour. Why should we be the only country that will take payment in any form the customer chooses?

One cannot help wondering where Mr. Anderson has been living for the last 10 years. Has he never seen goods "Made in Germany," or had to cut his prices in competition with a foreign firm? If he disregards the American competition of the recent past, and the German competition of the present, I suppose it is no use to suggest to him probable trouble from Japan in the near future.—I am, &c.,

Norwich, July 27. S. E. GLENDENNING.

THE DOLTER SURFACE CONTACT SYSTEM AT TORQUAY.

Our readers will remember that there has been a good deal of dissatisfaction in regard to the working of the Dolter surface contact system at Torquay, and that the Board of Trade recently decided not to renew the certificate under which the line was being worked. We have now received a copy of a report by Messrs. Mordey & Dawbarn to the Town Clerk of Torquay on the position of affairs, and in what follows we give an abstract of this report. The instructions received were to report (*a*) whether the present Dolter system could be improved and perfected so as to render it satisfactory, and (*b*) whether any other surface contact system could be substituted which would be satisfactory. The answer given to both of these questions is in the affirmative. Mr. Mordey visited the town in order to inform himself of the working of the system there, and also had an interview with Mr. T. B. Holliday, the engineer and manager of the Hastings Tramway Co., where the Dolter system is also being used. The report states that :—

The defects may be divided into those which cause dead studs, or studs which do not make connection between the cable and the car—or

Digitized by Google

which are sluggish and do not make the connection quickly enough—and live studs, or those in which this connection is maintained more or less perfectly when no car is present. The principal external evidence of unsatisfactory working was the frequent flashing or arcing between the collector skate and the studs, and the flickering—or more often the complete extinction—of the lights in the cars at night, due to dead or sluggish studs. Some of these defects are caused by insufficient magnetisation of the collecting skates. When there are two or three dead studs together, the car can get no current. When a car by its momentum runs over such studs, or over two or three sluggish studs, the circuit is interrupted, the motors get no current, and at night, the lamps are momentarily extinguished. The number of these dead or sluggish studs may be illustrated by the fact, that on one journey of about a mile along the Torbay-road, there were no less than 63 total extinctions of the lamps. And on some other sections of the line, especially on down gradients, the extinctions were so frequent that it was not possible to count them. In spite of this condition, the cars were very seldom unable to start. Mr. Mordey saw only one such stoppage, the car having to be crow-barred a few feet to reach a working stud. This may be taken as evidence, that many of the studs which do not act when the cars are moving quickly, are merely slow in action. Many of them would probably respond sufficiently quickly to a more strongly magnetised skate.

After referring to the cause of arcing and of live studs generally, the report proceeds:

On two separate occasions when Mr. Mordey was present, a car was not stopped when the detector bell rang. This detector, consisting of a trailing wire brush which is carried by the car, indicates by means of an electric bell, the presence of live studs. This device appears to be quite effective, except in the case of some of the curves, where it was noticed the brush was not wide enough to reach the studs as the car passed round the curves. This could easily be remedied. The dead studs are much more numerous than the live ones. There have been a good many cases of horses receiving shock, and it was stated that two or three horses have been killed. It is known that horses are very susceptible to electric shock, and with the line in its present condition, it is not surprising that there have been complaints from this cause. We understand that there has only been one complaint of shock to a human being, and the effect in that case does not seem to have been at all serious.

Although these various faults are of very frequent occurrence, they do not seem to interfere with the traffic. The attention that is given to the studs is apparently just enough to prevent loss of revenue. We are of opinion that the number of the faults is largely increased by the fact that so many studs are allowed to remain in a known defective condition. For example, the presence of dead studs greatly increases the liability of the adjacent good studs to break down by throwing on them an unduly heavy load. The engineer stated that only three men were employed on the road on the upkeep of the studs.

Messrs. Mordey & Dawbarn understand that the company bases its claim to abandon the surface contact system and to install the overhead trolley system on the high cost of working the former. This is not borne out by a comparison with three other typical places having heavy gradients, viz., Bradford, Halifax and Huddersfield. Costs are also given for Wolverhampton and Lincoln, where surface contact systems are in use. Experience shows that the energy taken by the collectors is not large, and that surface contact systems do not take appreciably more energy than trolley systems. The engineer informed Mr. Mordey that leakage amounted to 0·7 to 1 ampere per mile of track. Traffic costs are also lower than the average of 19 tramways having car mileages comparable with that of Torquay. The management and general expenses at Torquay are rather high, but this is not due to the system. The cost of repairs is less than for the average three hilly towns mentioned. The cost of power is high, but this is not due to the system, and the price charged, namely, 1·57d. per unit is very reasonable. The report proceeds further:

The defects found at Torquay, which have led the Board of Trade to intimate its intention to withdraw its licence, must be regarded as matters of detail rather than of principle and are capable of being met by an improved working of the system without any necessity of changing the system. We believe that by greater care and attention, the present studs could, without prohibitive cost, be made to work satisfactorily and if there were no reasonable alternative to this course, we think it would enable the company to satisfy the Board of Trade. We find, however, that an offer has been made to replace the parts of the stud which have given trouble by a simplified and improved modification. This offer, of which you have been informed, has been made by Mr. E. A. Mitchell, who was the engineer to the company that put the system down. We have carefully studied this improvement and are of opinion that the studs, so modified, would give greatly improved results, and would be more easily maintained.

In conclusion Messrs. Mordey & Dawbarn state that Mr. Mitchell, the engineer of the company supplying the equipment, is willing to modify the studs at a cost of £590 per mile, or a total of £6,500, with a contract price for maintenance of the studs of 0·22d., or, including the maintenance of the collectors, 0·23d. per car mile, which is considerably less than the £10,000 which, it appears, the tramway company is prepared to spend in putting in a trolley system. They think that the company should be strongly urged to adopt Mr. Mitchell's proposal.

In regard to the second question, Messrs. Mordey & Dawbarn refer to the Lorain system at Wolverhampton and the "G.B." system at Lincoln, and state that if it were necessary to change the surface contact system at Torquay, which is not the case, there is no reason to doubt that either of these systems would give satisfactory results. Torquay presents special features, in that there are steep gradients, and that a short length of the line along the sea front is occasionally drenched with sea water. Messrs. Mordey & Dawbarn do not consider that these conditions would cause the Wolverhampton or Lincoln systems to be unsuccessful at Torquay, provided suitable precautions were taken.

In an appendix some particulars are given of the Dolter system at Hastings, where it is used on 4 miles of track along the promenade. Occasionally the sea washes over the road, in which case extra men have to be put on to keep the skate and collector equipment on the cars in order. The studs require a good deal of attention, and in the course of a year about half of them have to be taken out, repaired and put back. About 5 per cent. of the studs require replacing each year. Twenty cars are running, and a large part of the trouble with collectors and skates is probably due to the fact that the cars have to be adapted to the double service, skates having to be raised when they get on to the trolley part of the line. Mr. Holliday finds that the maintenance of the surface-contact part of the line is about double as much per mile as with the overhead, and there is also considerable expense in the upkeep of skates. Difficulties with live and dead studs are reduced to a minimum by careful attention. The studs that are reported as "alive" amount to about 7 per cent. of the total per annum. The detector works effectively. The causes of live studs, as at Torquay, are carbonised oil, water and contact levers sticking. In cold weather there are a greater number of live studs owing to increased viscosity of the oil. Hardly any explosions have been experienced. Dead studs are more common than live ones, about 43 per cent. of the former being reported in the course of a year.

PARLIAMENTARY INTELLIGENCE.

LONDON ELECTRIC SUPPLY BILL.

This bill, which constitutes the London County Council the purchasing authority in regard to the five remaining London electricity supply companies was read a third time in the House of Commons on Thursday last and a first time in the House of Lords on Monday.

LONDON UNITED TRAMWAYS BILL.

On Thursday last this bill came before the House of Commons Committee on Unopposed Bills (presided over by Mr. Emmott).

Mr. CRIPPS, for the company, explained that a number of rather onerous conditions for the protection of Richmond Corporation were imposed on the company by their 1902 Act authorising the construction of a tramway in Richmond, and the company had not thought it worth while to incur the expenditure involved. In 1909, however, the company were authorised to construct a tramway across Kew Bridge to link up with their system in Brentford. The Richmond tramway had, therefore, become desirable in order to avoid a hiatus in the system. Richmond Corporation had consented to the insertion of a clause in the bill enabling variations to be effected in the conditions imposed by the Act of 1902 as to the form of construction.

The Committee passed the bill, ordered it to be reported for third reading, and granted an extension of time for the Richmond tramway until Aug. 1, 1912.

LONDON COUNTY COUNCIL (TRAMWAYS & IMPROVEMENTS BILL).

The Select Committee of the House of Lords, presided over by Lord Clinton, concluded the consideration of this bill on Monday.

Amongst the proposals in the bill were tramways in south London along Effra-road and Dulwich-road to Norwood-road, and along the upper

Digitized by Google

part of Tooley-street to a point near London Bridge. The House of Commons Committee which previously dealt with the bill passed the latter proposal as submitted and the former in an amended form.

The Committee decided to pass the clause relating to the line from Brixton-road to Norwood-road, that Dulwich-road should be widened, and that Lambeth Council should contribute £200 or (if a smaller sum) one-fifth of the cost of the widening.

The CHAIRMAN said the Committee were convinced that the extension of the line of tramway down Tooley-street would be an undue interference with the traffic and the legitimate business carried on there by wharfingers and others and they declined to sanction it.

Mr. ERSKINE POLLOCK, K.C., explained the proposal to erect and maintain shelters for passengers at Stamford-hill, New Cross and at the Blackfriars end of the Victoria Embankment. The two first would cost from £200 to £300 each, and the last mentioned (which would be 180 ft. long) £1,800.

It was agreed between counsel that the limit of time during which the Corporation could not demand the removal of the Embankment shelter should be 10 years.

The Committee decided that the shelters should be erected, subject to the 10 years proviso in respect to the Corporation.

SCIENTIFIC RESEARCH.

In the House of Commons on Thursday last Mr. LYNCH asked the Prime Minister whether, in view of the extension of higher education in neighbouring countries of recent years, and in view of the vastness of the industrial results which had had their origin in scientific research, he would consider what means could be taken to give a stimulus to such research in this country; and whether he would raise the office of the President of the Board of Education to the level of importance of that of any other great Department of State.

In reply, Mr. ASQUITH said the Government always had in view the objects advocated by the hon. member. He did not see how they would be promoted by the suggestion made in the second part of his question.

Scottish Electric Lighting Orders.—A Select Committee of the House of Lords, presided over by Lord Clinton, last week decided to allow the Electric Lighting Orders (No. 2) Bill to proceed. The bill relates to electricity supply undertakings in Ardrossan, Saltcoats and Cambuslang.

Bath Electric Lighting Extension Bill.—On Thursday last this bill, promoted by Bath Corporation, and which has already passed the House of Lords, was sent by the Examiner for second reading in the House of Commons.

Provisional Order [Confirmation Bills.—The unopposed bills to confirm the electric lighting orders granted to Clevedon District Council and the Gorseinon Electric Light Co. were passed by the Chairman of Committees of the House of Lords last week, and ordered for third reading.

Miscellaneous Bills.—On Monday in the House of Lords the Middlesbrough Corporation, Rhondda Urban District Council (Tramways Extensions, &c.) and Bradford Corporation Bills were read the third time and passed.

Royal Assent.—On Tuesday the Royal assent was given to the London Electric Railway Amalgamation, Metropolitan Railway, Wimbledon & Sutton Railway, Baker-street and Waterloo Railway and other bills.

LEGAL INTELLIGENCE.

Limited Liability Companies and Private Generating Plant.

In the Chancery Division on Tuesday, Mr. Justice Joyce heard a petition by the Hendon Paper Works Co. (Ltd.), of Sunderland, to sanction the extension of its objects in various ways, including the generation of electrical power for the purposes of lighting and heating their works.

The application was opposed by the Town Council of Sunderland on the ground that by their provisional order of 1891 they had the sole right to supply electricity within the borough, and that the extension of the applicants' powers as asked would enable them to finance or run an electric lighting company and so seriously depreciate the value of the Corporation's undertaking.

Having heard the arguments of counsel, his lordship made the order asked for by the company.

Unfenced Machinery.—At Birmingham Police Court on Friday, the Electric & Ordnance Accessories Co. were summoned for failing to have a machine fenced as required by the Factory Acts.

It was stated that a youth named Thorneywork was engaged at a milling machine cutting metal, and on reaching to adjust an arm, which had not been protected by a guard, his sleeve was caught by the circular saw and his hand and arm severely lacerated. Mr. Gibbs, for the defence, submitted that the guard was not on the machine owing to the negligence of a workman. The clerk pointed out that defendants were not exempt on this ground unless they had secured a conviction against the workman, and an adjournment was granted to enable proceedings to be taken against the workman.

MUNICIPAL, FOREIGN & GENERAL NOTES.

APPOINTMENTS VACANT AND FILLED.

The governing body of the Northampton Polytechnic Institute London, invite early applications for the appointments of senior assistant in the electrical engineering department, to take charge of new electric generating station (salary 45s. per week); junior assistant in electrical engineering department, chiefly to take charge of producer plant (28s. per week); second lecture assistant in electrical engineering department (£80 per annum); and assistant lecturer and demonstrator in the mechanical engineering department (£120 per annum). The appointments will take effect after the summer vacation. Particulars from the office of the Institute or from the principal, Dr. R. Mullineux Walmsley. See advertisement.

The Council of the University of Birmingham invite applications for the appointment of assistant lecturer and demonstrator in electrical engineering. Candidates must be graduates, and must have had experience in the test room of first-class electrical engineering firm. Stipend £150 per annum. Applications to the secretary, Mr. Geo. H. Morley, by Sept. 17. See an advertisement.

Taunton Corporation require a borough electrical engineer. Commencing salary £200 and half pupils' premiums. Applications to the Town Clerk by 9 a.m., Aug. 4.

The Victoria Falls and Transvaal Power Co. require six shift engineers (£35 per month each), three boiler house superintendents (£35 per month), six senior switchboard attendants (£25 per month), and six junior switchboard attendants (£21 per month). Applications to the Secretary, 2, London Wall-buildings, London, E.C.

Applications will be received until Sept. 10 for appointment to the Henry Overton Wills Chair of Physics at Bristol University. Salary £600 per annum. Particulars from the Registrar.

A lecturer in mechanical engineering is required at Blackburn Municipal Technical School. Salary £120 to £140. Forms from the Director of Education. Applications by Aug. 13.

A teacher for evening classes in electrical engineering and magnetism and electricity is wanted for the Gt. Eastern Railway Institute, Stratford, London, E. Applications by Aug. 2 to Mr. T. O. Mein, Loco. Works, Stratford.

A second demonstrator in the department of chemistry is wanted at the City and Guilds of London Technical College, Finsbury, E.C. Salary £100, rising to £150. Applications by Sept. 1 to Prof. R. Meldola, F.R.S.

A lecturer in heat engines and in electricity applied to engineering is required for the Bedford Evening Institution. Salary (according to qualifications) up to £100 for the session (26 weeks). Applications to Mr. C. W. Kaye, Modern School, Bedford.

A sub-station attendant is required for Stepney electricity department. Commencing salary 30s. per week.

A Canadian publishing house advertise for an experienced editor for an electrical journal.

Alloa Council have appointed Mr. H. A. Tulloch as electrical engineer-in-charge of their electricity works, now in course of erection. Mr. Tulloch has been five years with Bruce Peebles & Co. and was for some years resident engineer of the Electric Supply Corpn.'s station at Dalkeith.

Mr. R. B. H. Craig, of Bermondsey, has been appointed assistant electrical engineer to Watford District Council, Mr. G. D. Vickers, who had been appointed, having withdrawn his application.

Mr. A. R. Sillar, formerly borough electrical engineer of Colchester, has been appointed by the Chinese Chartered Electrical Co. as chief electrical engineer of their electricity undertaking at Peking, China.

Mr. J. H. Havelock, A.M.I.E.E, Liverpool, has been recommended to the Kent Education committee for appointment as assistant master in the electrical department at the Gillingham Technical Institute at a commencing salary of £120.

The Engineering and Chemistry committee have unanimously agreed to recommend the governors of Robert Gordon's Technical College, Aberdeen, to appoint Mr. Alex. R. Horne, of Heriot Watt College, as head of the engineering department. The salary is £500.

Swansea Town Council on Wednesday appointed Dr. J. Mansergh Varley (principal of Devonport Technical School) as principal of Swansea Technical College, at a commencing salary of £500. Dr. Varley is 31 years of age. The final selection was made from the following six candidates:—A. B. Badger, M.A., B.Sc., J. H. Grindley, D.Sc., W. J. Lineham, B.Sc., W. L. Templeton, M.A., J. Mansergh Varley, D.Sc., and J. H. Vincent, D.Sc.

Digitized by Google

On Tuesday Birmingham City Council approved the appointment of Mr. Howard Foulds as secretary of their electric supply department (referred to in our issue of July 15).

EDUCATIONAL NOTICES.

City and Guilds of London Institute.—The entrance examinations of the City and Guilds Central Technical College, Exhibition-road, S.W., and the City and Guilds Technical College, Finsbury, E.C., are held in September, and the sessions commence in October.

Both institutions provide courses of instruction in engineering, chemistry, mechanics and mathematics, &c. Particulars of entrance examinations, scholarships and courses of study may be obtained from the respective colleges or at the head offices of the Institute, Gresham College, Basinghall-street, London, E.C. The Central Technical College is intended for higher technical instruction for day students not under 16 years of age, preparing to become civil, mechanical or electrical engineers, chemical or other manufacturers and teachers. The college is a school of the University of London, and forms the engineering section of the Imperial College of Science. The courses of the study for the associateship of the Institute cover a period of three years.

The City and Guilds Technical College at Finsbury (London, E.C.) is designed for day students preparing to enter engineering and chemical industries and for those who have already served an apprenticeship and also for evening students. The day courses in mechanical or electrical engineering cover two years and those in chemistry three years.

City and Guilds of London Institute.—At a meeting of the council on Wednesday the diploma of "Associate of the City and Guilds of London Institute" was awarded to 80 matriculated third year students of the Central Technical College who have completed a full course of instruction as prescribed by the Council, viz., 50 in civil and mechanical engineering, 25 in electrical engineering and 5 in chemistry. The following are the names of the students in electrical engineering:—

J. D. Peattie (awarded Siemens Memorial Medal and Premium), M. de Angelis, W. S. G. Baker, W. Barrs, P. R. Blamey, H. Clark, H. M. Dunkerley, D. H. Green, W. C. Griffith, G. E. W. Hitchcock, A. E. D. Kennard, G. Lambert, A. W. M. Mawby, P. A. McGee, D. J. McHatton, R. F. Niven, N. J. Perryman, L. C. Pocock, F. C. L. Racker, N. N. Roy, L. L. Ruderman, J. McL. Thornton, G. H. Tilly, F. J. Vinsen, and G. Watts.

In addition to the above, certificates have been awarded to 19 matriculated third year students who have completed a full course of instruction at the Central Technical College and to 56 students who have completed a full course of instruction at the Technical College, Finsbury.

University of London. University College.—The 1910-11 session begins on Monday, Oct. 3. Students desirous of entering the faculty of engineering with the view of taking a full degree or diploma course must have passed the matriculation examination or some other examination accepted in its stead. The fee for the full three-year diploma course in engineering, including the course for graduation (B.Sc.) in the faculty of engineering, is 120 guineas (payable in three instalments). Students who have already attained a sufficient standard may enter for a course occupying less than three years, and may obtain a general certificate of engineering after not less than two consecutive sessions. Graduates in science or engineering or students who have done the work equivalent to a degree may be admitted to special courses of study or to prosecute original research. Full particulars from the secretary, Mr. Walter W. Seton, M.A. Intending students should communicate with the Provost as soon as possible, and in any case not later than Sept. 20.

University of Birmingham.—The session 1910-11 commences on Monday, Oct. 3. The full courses in the engineering department extend over four years, and students who enter after matriculation and who pass successfully the examinations at the end of each year will be entitled to the degree of Bachelor of Science in the branch of engineering to which they devote themselves. The technical engineering classes include lectures on the strength of materials, theory of steam, gas and other heat engines, hydraulics, machine design, strength of structures and distribution of power, design of tools, prime motors, dynamos, &c. The courses in civil engineering cover a wide range. Lectures and demonstrations are given on all branches of electrical engineering and the electrical laboratory work comprises the testing of c.c. and a.c. machinery, instruments, meters, lamps and batteries and insulation and magnetic testing. The courses also include mathematics, physics, chemistry, geology and metallurgy. Syllabus, &c., from the Secretary.

University of Liverpool.—The session 1910-11 commences on Tuesday, Oct. 4. The courses of study in the faculty of engineering leading to the ordinary degree of Bachelor of Engineering extend over at least three years, and are so arranged as to afford a general scientific training for those who intend, with or without graduating, to become engineers, naval architects or architects and surveyors. Students who do not proceed to a University degree may take a course of not less than two years, leading to a certificate in engineering. The honours schools enable students to specialise in some branch of the profession, and opportunities are afforded for post graduate work and research. Prospectus of the faculty can be obtained from the Registrar, Mr. P. Hebblethwaite, M.A.

Wigan and District Mining and Technical College.—We have received a copy of the calendar of this college for the 54th (1910-11) session, which commences on Sept. 12. The book contains excellent interior and exterior views. The contents include lists of the members of the governing body, the teaching staff (of whom Mr. T. T. Rankin is the principal and Mr. H. G. Cotsworth the head of the electrical engineering department), the equipment of the laboratories and workshops, &c., and particulars of the courses. The sandwich system is adopted, a portion of each summer being spent in mines or mechanical or electrical engineering workshops. Details are given of the curriculum in the departments of practical mathematics, mechanical engineering, engineering and machine drawing, electrical physics, electrotechnics, chemistry of mining, metallurgy, assaying, coal and metalliferous mining, mine surveying, geology and mineralogy. There are also day apprentice classes, a pupil teacher department and special Saturday mining classes for colliery managers, firemen and shotlighters. The book is issued at 6d., post free.

Northampton Polytechnic Institute (London).—Full day courses in the theory and practice of mechanical and electrical engineering and electro-chemistry will commence on Monday, Oct. 3.

The courses in mechanical engineering include specialisation in automobile and aeronautical engineering, and those in electrical engineering include specialisation in radio-telegraphy. The entrance examination takes place on Sept. 28 and 29. Three entrance scholarships of the value of £52 each will be offered for competition at the entrance examination. The courses include periods spent in commercial workshops and extend over four years. They also prepare for the degree of B.Sc. in engineering at the University of London. There are full and part time courses in all branches of technical optics. Particulars as to fees, &c., can be obtained at the Institute, Clerkenwell, E.C., or on application to the principal, Dr. R. Mullineux Walmsley.

Armstrong College, Newcastle-on-Tyne.—The next session commences on Sept. 26. The matriculation examination takes place on Sept. 20-23. There are full courses of instruction in mechanical, marine, civil and electrical engineering, naval architecture, mining, metallurgy, agriculture, pure science, arts and letters. Particulars from the secretary, Mr. F. H. Pruen, M.A., Armstrong College, Newcastle-on-Tyne.

University of Glasgow.—The next session will commence on Oct. 17 and end on March 23, 1911. In the departments of engineering, mining and naval architecture students usually spend the summer months in practical work, thus receiving their training on the Sandwich system. Prospectus of the course for the degrees of B.Sc. and D.Sc. in engineering and syllabus of classes may be obtained from the Assistant Clerk, Matriculation Office, The University, Glasgow

University of Manchester.—A prospectus giving particulars o the lecture and laboratory courses in physics, preparing for both the ordinary and honours degrees, will be forwarded on application to the Registrar.

BRITISH NOTES.

Amersham.—The Uxbridge & District Electric Supply Co. propose to transfer their undertaking to Callender's Co. and the latter are applying for a provsional order for Amersham Rural District.

Ashton-under-Lyne.—In a recent issue of a local journal there appeared an interesting letter advocating the use of water power, which appears to be available in the neighbourhood, for the generation of electric current.

The writer stated that there was sufficient water power running to waste within a mile of the Ashton tramway system, which, if efficiently harnessed and utilised, would save the burning of some 2,000 tons of coal yearly. That power could be had at a capital outlay not exceeding £5 per horse-power and working 8,000 hours in the year would yield about 1,500,000 units yearly, and could be obtained at ¼d. per unit (including working expenses, interest and depreciation). Within 8 miles of Ashton there is (continued the writer) a situation where some 500 H.P. was also running to waste. That was (according to the writer) an ideal power site provided by nature, for, in addition to the 500 H.P. there was abundance of virgin coal on the spot (one or two seams outcrop on the surface). Some time ago the site could be had for £50 per annum, which worked out at about 2s. per horse-power per year, and coal at 1s. per ton could not compete with that power, as the water would flow into and out of turbines by its own gravity. There being no coal to handle, fires to scale or cinders to clear away, consequently one man could with greater ease attend 2,000 H.P. (water) than a man could take

Digitized by Google

care of 500 H.P. (coal). The writer suggested that the Ashton Council should acquire a site. There was a very suitable one where some 150 H.P. could be relied on 300 days in the year, the cost of developing and installing turbines would be from £600 to £700, the rent should not exceed £15. Power from that site would give 700,000 units yearly, and at a ¼d. per unit would save the corporation £972 (estimating cost of Ashton's current at 1d. the unit), and would save the burning of some 937 tons of coal yearly.

Aston.—Mr. H. Ross Hooper held an inquiry on Friday last into the application of the Corporation for permission to borrow £23,500 for the electricity department.

The difference between the tenders received and the estimates caused a reduction of the amount to £23,105. Of this amount £12,515 is for plant and machinery, and £10,590 for mains and services, and the Council asked that £6,000 of the last-named amount should be spread over their requirements for the next two years—viz., £4,500 for mains and £1,500 for services.

The INSPECTOR said the profits last year were eminently satisfactory, but asked if anyone could show him where the advantage came in of transferring to the reduction of the rates £1,500 with one hand and borrowing £1,500 with the other for an expenditure for like services, which was continually going on. It was no advantage to the ratepayers and no advantage to the undertaking. To borrow money with one hand at 3¼ per cent., and to pay it out as a bonus with the other, meant that the ratepayers had to pay the 3¼ per cent.

Mr. GODRICH (chairman of the Electricity committee) said they had acted in the interests of the ratepayers, the rates having been reduced in consequence of the contributions from the electricity undertaking.

Mr. HOOPER said it was only the well-to-do people who got the benefit of the reduction at a cost to the general undertaking. He asked them to withdraw that item, or put it down to mains, making the total for that purpose £6,000.

The latter suggestion was agreed to, and the inspector remarked that in future cost of services would be debited to revenue.

Ballyclare (Ireland).—The Council have decided to accept the offer of Messrs. Curran Bros. for supply of electric light in the town, subject to a satisfactory agreement.

Barnstaple.—The Council have adopted a minute of a special committee that "further expenditure on account of advertising or exhibitions on electricity account is undesirable until satisfactory arrangements have been made for the proper display and supply of fittings and further facilities afforded for wiring the premises of prospective consumers."

Coun. WHITE said he understood the committee had made various attempts to get someone in the town to take up the supply of electric fittings, and wiring of premises generally, on similar lines to those followed by the gas company. They had been unsuccessful. The committee was still on the look-out for an enterprising firm to undertake the work.

Bermondsey (London).—The Finance committee report that they have considered the accounts for the year ended March 31, together with the estimates for the current year, of the Electricity and Street Lighting committee.

The committee call the Council's attention to the fact that, on the year's working, with an outstanding loan indebtedness of £152,973 the surplus is only £43, against an estimate of £500. In their opinion the result is partly due to the very low price at which energy is being sold, and they think it behoves the Council to be careful as to how the undertaking is managed in the future, more especially with regard to the incurring of further capital liability. The current year's surplus is estimated at £600.

The Electricity committee report that with reference to the report presented by them to the Council at its last meeting, with respect to the quinquennial valuation of the electricity works at gross £3,399 and rateable £2,266 against the present figures of gross £2,693 and ratable £1,796, London County Council object to the proposed valuation of the electricity works and they claim a correction to gross value £8,000 and ratable value £3,000.

Birmingham.—The City Council on Tuesday authorised application by the Corporation for powers to construct and work a section of light railway in Beech-lane from the King's Head to the corner of Balden-road, and to complete it ready for inspection simultaneously with completion of the Hales Owen light railways, and to purchase the portion of the line between Balden-road and Quinton.

Bradford.—At the Valley-road electricity works on Wednesday the formal starting took place of two new 3,000 kw. Curtis turbines and alternators.

The turbines take steam at 180 lb. pressure per square inch and at 500°F., and utilise it until it is exhausted into the condenser at 13·5 lb. pressure. The a.c. current generated is 6,600 volts. All the work has been carried out to specifications and designs prepared by Mr. T. Roles, city electrical engineer. The principal contractors for the installation were the British Thomson-Houston Co., of Rugby, who made the turbines and alternators, and the sub-contractors for the condensing plant were the Worthington Pump Co., who manufactured the condensers and air and ventilating pumps; Thornton & Crebbin for the hydraulic accumulators and the main circulating pipes; Sheepbridge Coal & Iron Co. for pipes; Pearn & Co. for footstep pumps; Aiton & Co. for the piping in the engine room; Babcock & Wilcox for steel steam pipes and separators, and Messrs. Brook, Hirst & Co. for switch pillars. Other contractors, directly responsible to the Corporation, were Henry Barrett & Sons, engine-room floor; T. Obank & Sons, foundations and masonry work; S. Parsons & Co., steel towers carrying the circulating water pipes; Stewarts & Lloyds, steam pipes; E. & W. H. Haley, cast-iron connecting pipes, &c; and Sloan & Davidson, staircase connecting engine room and basement floor levels.

Brierfield.—The Council have decided to accept the offer of Nelson Corporation to supply electrical energy in Brierfield for lighting at 2½d. and for power at 1½d. per unit.

Camborne.—The Council have consented to an application by the Urban Electric Supply Co. for a provisional order for the Dolcoath Mine.

Cardiff.—The Tramway committee have decided to purchase 130 tramcar current meters at £3. 5s. each.

Chartered Institute of Patent Agents.—The qualifying examination of persons desirous of being registered as patent agents will be held in November next. A notice, giving particulars, appeared in the "Illustrated Official Journal (Patents)" of July 6, 1910, and a copy of the notice can be obtained from the Secretary of the Chartered Institute of Patent Agents, Staple Inn-buildings, London, W.C.

Church Lighting.—The electric light was used for the first time in Christ Church, Epsom, on Sunday, July 17. The cost of the wiring and fitting was £120.

Cirencester.—Mr. J. H. Edmonds is applying for a provisional electric lighting order.

Clutton (Bristol).—The Western Electric Distributing Corpn. have notified the Rural Council that they will apply for a provisional order.

Coventry.—The Education committee are having three schools lighted electrically, and if the experiment is satisfactory will also adopt electric lighting in other schools.

Fleetwood.—Permission is being sought to permit the Council to proceed at once with extensions of their electricity undertaking. Large demands for current are in hand and new machinery will be required during the ensuing winter.

Frodingham.—The Council have decided to go on with the electric lighting of the streets at Frodingham.

Fulham (London).—The assessment of the electricity works and appurtenances, at present assessed at £2,850 gross and £1,900 ratable value, has been inserted in the new valuation list at £10,500 gross and £4,500 ratable value.

Notice of objection will be given. London County Council have lodged notice of objection on the ground that the values should be £14,000 gross and £5,600 ratable.

The Electricity committee propose to supply current to lamps in the halls and staircases of maisonettes at a fixed rate. In such cases hour meters are to be provided instead of the usual recording meter, and, estimating that 1,640 hours per annum will cover the use of one lamp, the charge at 3½d. per unit, using an 8 c.p. carbon lamp, works out at 16s. 9d. per lamp per annum. For all current consumed in excess of 1,640 hours a further charge of 3½d. for every 30 hours, or portion of 30 hours, will be made.

Heston and Isleworth.—The Council have authorised the Electricity committee to make arrangements with approved electrical contractors for the engagement of canvassers, to be paid by contractors, and to take instructions from the Council's electrical engineer, the contractor to be paid a commission of 10s. per kilowatt for lighting and 5s. per kilowatt for power installations.

Hindley.—The question of the revocation of the Council's electric lighting order has been postponed for 12 months by the Board of Trade.

Gosport.—After July 31 the tramway routes are to be lighted by electricity instead of gas.

Hindley.—The Board of Trade have granted an extension of one year for carrying out the provisions of the 1901 electric lighting order.

Hospital Lighting.—Electric lighting is to supersede gas lighting at Hyde Corporation Hospital.

Ilkeston.—At a recent meeting of the Council Mr. Coun. Moss asked whether the Corporation were prepared to consider an offer for the purchase of the tramway system.

The MAYOR, in reply, said it was a matter that could best be considered by the whole Council in committee, and a special meeting was accordingly held, when it was unanimously decided not to entertain any offer for the disposal of the tramways.

Several members pointed out that although the cars were not actually showing a profit they were a great boon to the ratepayers, and if the control went out of the hands of the Corporation the convenience of the public would be a minor consideration. The Mayor stated that since

Digitized by Google

the new manager, Mr. Stokes, had taken up his duties the service had been considerably improved and a great deal of reconstruction work carried out. There was every prospect of an improvement in the financial position of the concern. During the nine months Mr. Stokes had been in Ilkeston he has reconstructed two route miles of overhead work and one mile of track.

Inquest.—A verdict of accidentally electrocuted was returned at an inquest held at Blaydon last Saturday. A deputy overman named Barrett, aged 48, met his death at Blaydon Burn Colliery.

According to the evidence, Barrett was engaged leading water in a drift of the mine when the telephone bell rang. Barrett attending the call, received a shock on taking hold of the receiver. He was unable to leave hold of the instrument, and was afterwards found lying dead. The head electrician, Mr. Hall, explained that a steam pipe had recently been placed in the drift. Below this was an iron pipe, containing a cable for conducting a supply of electricity to the pick-sharpening shop. The steam pipe had evidently come in contact with the iron pipe, and the pressure had caused one of the joints to break, with the result that the insulation of the cable was damaged, and the current (250 volts) traversed the telephone wire. This was not sufficient to kill a man instantaneously and it was probably the continuousness of the current which had proved fatal to Barrett.

Launceston.—The Council have asked the Board of Trade not to revoke their 1903 electric lighting order, as they are considering an electric lighting scheme submitted by Mr. J. A. Purves.

London County Council.—At their meeting on Tuesday the Council adopted a report of the Finance committee in reference to loans to Islington Council for electricity mains.

The report states that Islington Council has in hand unexpended balances amounting to £35,765. 2s. 7d. in respect of loans for mains. The balances result from loans being obtained in advance of expenditure and the subsequent abandonment of some of the work, while other work for which the loans were granted has been carried out for less than the estimated cost, or has been deferred. The practice of the Borough Council in recent years has been to obtain sanction to loans in respect of current capital expenditure, but, instead of borrowing immediately under such sanctions, to utilise unspent balances of former loans. At the present time the borough Council has in hand unexercised sanctions to loans for electricity purposes amounting to £32,498. It appeared to us (continues the report) that this was far from satisfactory, and we communicated with the Borough Council; and the Borough Council suggest that the £35,765. 2s. 7d., should be repaid to the Council; and that the Borough Council should borrow from the Council, at a rate of interest equivalent, as nearly as might be, to the rates payable on the loans of which the unexpended balances form part, such an amount not exceeding the amount to be repaid as might be deemed necessary, and that for this purpose the sanctions in hand and those to be obtained for capital works executed in 1909-10 should be utilised. We suggest that the proposal of the Borough Council be agreed to. The rate of interest equivalent to the rates on the sum of £35,765. 2s. 7d., now to be paid off, is £3. 11s. 6d. per cent. The total of the outstanding sanctions for electricity purposes is £32,498, and the Borough Council desires that the advance of this sum should now be made on the terms agreed, repayment to be on the annuity system.

"The Borough Council also has in hand a sum of £5,042 unspent in respect of a loan of £7,468 (part of £45,206) for street lighting, advanced on Nov. 11, 1904, and it desires the Council to accept repayment of this sum in reduction of the loan. The total amount which the Borough Council wishes to repay is therefore £40,807. 2s. 7d."

The report goes on to recommend that an arrangement on the lines proposed should be carried out, and the loan of £32,498 granted, to be repayable as to £3,942 for purchase of freehold property within 60 years, as to £10,204 for mains within 30 years, as to £9,572 for machinery within 20 years, as to £3,685 for house services within 12 years, and as to £776 for mains, £3,200 for machinery, and £1,119 for meters within 10 years

L.C.C. Tramways.—London County Council has written Islington Council that, in view of the difficulties which have arisen between the Hackney and Islington Councils and the County Council in connection with the proposed Ball's Pond-rd tramways, the County Council has decided not to proceed with the proposals contained in the London County Council (Tramways and Improvements) Bill, 1910, with regard to the widening of that thoroughfare.

The new section of tramway between Woolwich and Eltham, which is worked on the overhead trolley system with an overhead return wire, was inspected by Major Pringle and Mr. A. P. Trotter on Thursday and opened for traffic on Saturday.

London Street Lighting.—Holborn Borough Council have referred back a report by the Works and General Purposes committee recommending the acceptance of an offer by the Gas Light & Coke Co. to light the borough throughout by inverted incandescent burner gas lamps. The Council requested the committee to obtain competitive prices.

Obituary.—The death is recorded on July 20 of Mr. Thomas Hurley (Messrs. Gent & Hurley). Mr. Hurley was in his 70th year.

Oldham.—The Corporation are prepared to give a supply of electricity to Alt in the Limehurst area, provided the Council of the latter district give their consent. The Lancashire Electric Power Co. also possess supply powers for the district.

Personal.—Mr. A. S. Esslemont, who has been for many years manager of the County of Durham Electric Power Supply Companies, will shortly resign this position in order to specially devote his time to the development of electro-metallurgical and other processes on Tyneside on behalf of the Newcastle-on-Tyne Electric Supply Co.

Mr. Arthur Greenwood (Messrs. Greenwood & Batley) has been appointed a director of the North Eastern Railway Co., to fill the vacancy caused by the death of Mr. Hy. Tennant.

Provisional Order Revocation.—The Board of Trade have revoked the Strood and Dartford (Rural Districts) Electric Lighting Order, 1903, as from July 18.

Sevenoaks.—On the recommendation of the Lighting committee (which has considered Messrs. Mordey & Dawbarn's report on the subject), the Council decided to apply for a provisional electric lighting order.

Southend.—A L.G. Board inquiry was held on Tuesday into the application of the Corporation for permission to borrow £20,467 for the electricity department. The purposes for which the money is required include the construction and equipment of two substations to serve the Chalkwell and Southchurch districts. There was no opposition.

Theft of Electricity.—At Manchester Police Court J. F. Churchard, of Second-avenue, Trafford Park, was fined 20s. and costs for fraudulently using electricity, the property of the Trafford Power & Light Supply (Ltd.), to the value of £1. 3s. It was stated that the prepayment meter was 73 tokens short (each token costing 3½d.). The meter was found to be in perfect order. Defendant admitted having inserted a wire, but said it was done in innocence. He had only done what others had done when they could not get any light.

Torquay.—Mr. H. Ross Hooper held an inquiry on Saturday into the application of the Corporation to borrow, amongst other sums, £3,500 for their electricity department.

The town clerk (Mr. F. S. Hex) explained that the money was required for the extension of the lighting mains to Chelston, to provide for further extensions and to cover excess expenditure of £525. It was decided to increase the amount applied for to £4,500, and the inquiry was closed.

Walsall.—The Council on Tuesday adopted a report of the Electricity committee recommending additions to the plant at the electricity works and extensions of mains to Birchills, Bescot and Bloxwich, at a cost of £23,225. The proposal to build a new generating station has been abandoned.

Walthamstow.—The Council are applying for sanction to a loan of £1,838 for mains extensions, house services, &c.

West Ham.—Mr. H. Ross Hooper held an inquiry on Wednesday into an application by the Corporation for permission to borrow £53,500 for the electricity undertaking.

It was stated that there were overdrafts on capital account of £71,730. The capital expenditure on the undertaking to March 31 last was £490,668, of which £15,553 had been contributed out of revenue. Mr. Elvey Robb representing the India Rubber, Gutta Percha & Telegraph Works Co., large ratepayers in the borough, said his clients had pending an action against the Corporation, who had given them no intimation that this inquiry was to be held. He questioned Mr. Couzens, the borough electrical engineer, as to the policy of supplying power consumers at 1·37d. per unit, and Mr. Couzens maintained that it was beneficial to the undertaking. The inspector eventually said he would report to the L.G. Board, and leave it to them to decide if a further inquiry should be held.

Wireless Telegraph Notes.—Whether or not it is found to be correct that the notorious Dr. Crippen and Miss Le Neve are on board the "Montrose" when she reaches Canada, or even if the arrest takes place in mid-ocean, it is to the credit of wireless telegraphy that it has been the means of placing the police on to a clue, which would have been impossible only a few years ago. The future has many added terrors for the criminal, for wireless telegraphy places a powerful weapon in the hands of the police authorities.

In another direction this week wireless telegraphy has served the highest purpose. 83 passengers and 125 members of the crew of the South Pacific Line steamer "Momus," bound for New Orleans from New York, were threatened with a terrible death at sea. The vessel caught fire, owing, it is said, to the carelessness of a passenger, and but for the wireless apparatus on board, all might have been lost. A sister ship, the "Comus," on the return journey, received the signal for help and was able to give ample assistance.

Workhouse Lighting.—The Canterbury Guardians are considering the question of lighting the workhouse electrically.

Digitized by Google

"Electrical" Bowls.—The first annual bowling competition on a green constructed in a portion of the works yard of the St. Helens Cable Co., at Warrington, took place on Saturday. There were 84 entries, and the prizes were sets of bowls presented by Mr. T. O. Callender and Mr. James Taylor, directors. The green, which was laid out by the staff, accommodates six games simultaneously.

Football.—The Electrical Football League have a few vacancies for clubs connected with the electrical industries. Particulars from Mr. C. Phillips, 140, Minet-avenue, Harlesden, N.W. Referees with vacant dates please write to Mr. Fraser, 100, Bishop-road, Fulham, S.W.

COLONIAL AND FOREIGN NOTES.

Brazil.—The "Financial Times" contains particulars of a concession for electricity supply stated to have been granted to the Brazilian Electric Power Co.

The right to commence the supply of current generated by water power does not come into force until June 7, 1915 (the date upon which the concession held by the Rio de Janeiro Tramway, Light & Power Co. expires), unless the exclusive rights of the Rio de Janeiro company are previously extinguished. The latter, a Canadian company, is the only one at present in the field, and the concession to the Brazilian Company has been granted by the Prefecture of the Federal District of Rio de Janeiro, in accordance with the policy of free competition recently re-affirmed in a message delivered by the President of the Republic. The period of the new concession is 24 years.

Upon subsequent inquiry from the secretary of the Rio de Janeiro Tramway, Light & Power Co., the "Financial Times" learns that the Directors of that company have obtained an injunction in the High Court of the Brazilian Republic restraining any interference with their rights, and that the Prefect has, as a result of representations made by the Tramway Co. stated that he will protect their rights and restrain others from infringing their concession. The validity of the rights to which the parent company lays claim through its subsidiaries has been tested on various occasions in the Brazilian Courts, and in every case the verdict has been given in the company's favour.

Chili.—Consul E. F. Hudson, in his report on the trade of Iquique in 1909, intimates that the articles used in connection with the Chili nitrate industry include boilers, cooling tanks, electric light plants, light portable railways, &c.

Cuba.—The imports during 1907-8 included electric lamps, valued at $35,217 from the U.S.A. and from other countries $8,821.

Customs Duties.—A recent supplement to the Australian Customs Tariff Guide states that it has been decided that insulated bolts for fastening trolley wires to the wire supports, jars (other than glass) and zincs for electric cells, and vulcanite cells for galvanic cautery batteries are subject to an import duty of 17½ per cent. (British goods 10 per cent.); on paper discs for antiseptic attachments for telephone transmitters the duty is 30 per cent. (British 25 per cent.), while metal frames for the same attachments and electric valves for protection against resonance (British or other) are duty free. On tramcar platform gongs and sand boxes for tramcars the duty is 35 per cent. (British 30 per cent.)

A recent circular of the Servian Minister of Finance determines that No. 645 of the Servian Tariff of import duties (the duty being 75 dinars per 100 kilogs.) includes all electric light fittings not mentioned elsewhere (whether mounted or not), the only exception being porcelain insulators combined with iron and keys; and that the second paragraph of the same number (120 dinars per 100 kilogs.) includes Geissler and other similar tubes and lenses for Rontgen rays and other purposes.

India.—"Indian Engineering" says the construction of the Mussoorie electric tramways will be undertaken shortly.

A trial of electric light has been made in the Mall, Simla, with a view to ascertaining the cost of lighting the station electrically. The municipality have obtained a licence under the Indian Electricity Act.

The "Indian and Eastern Engineer" states that Lahore Municipal committee will shortly consider a scheme for lighting the city and the civil lines electrically.

The 1909 report of the Railway Board states that 480 railway carriages were fitted for electric lighting and 778 for gas during the year, making a total of 15,237 fitted for electricity or gas and leaving 5,071 not fitted.

Japan.—Acting Consul A. R. Firth says applications have been addressed to the Formosan Government by three rival groups for a concession for the construction of electric street railways in the city of Taihoku, which has a population of 84,000.

Mexico.—The report of Consul-General Stringer states that British capital has been invested on the Conchos River, near Santa Rosalia, for impounding the water of that river by a great dam, and it is intended to develop some 30,000 H.P. for the mining districts of Naica, Almolya, Parral, Santa Barbara and adjoining places, and to carry out irrigation work. The preliminary work is in hand.

Vice-Consul C. G. Scobell says that Chihuahua offers to capitalists who are interested in mining or industrial enterprises great opportunities for investment. It has waterfalls and great resources in minerals. The State Government is in communication with almost every part of the State through an efficient system of telegraphy.

Vice-Consul P. G. Holms (Guadalajara) says the introduction of electric power into the Hostotipaquillo district at £10 per horse-power per annum will enable immense reserves of low-grade ore to be utilised. Steam power formerly cost over £25 per horse-power. An amalgamation of power interests has resulted in the formation of the Chapala Electric & Irrigation Co., with a capital of $14,000,000 (Mexican currency). The Federal Government lends the company $3,000,000 (£300,000) for constructing a dyke across a portion of Lake Chapala, which will be the first step towards reclaiming about 123,500 acres, with a value of $12,500,000 (£1,250,000). The company has concessions which will enable it to generate over 100,000 H.P. from the Santiago River, an effluent from Lake Chapala. Power sells at from $100 (£10) to $125 (£12. 10s.) per horse-power per annum. Mining districts will absorb a fair amount of power in the Hostotipaquillo and other camps. The company will supply Guadalajara with power, and a contract has been signed to run transmission lines and power to the city of Aguascalientes, while it is possible that power may also be carried as far as Zacatecas.

Vice-Consul R. M. Cormack (Guanajuato) says a British subject owns a large electric light and power plant at Colaya, from which power and light is supplied to several neighbouring towns. The Guanajuato Power & Electric Co., who control the electrical situation in the States of Guanajuato, Michoacan and San Luis Potosi, have recently placed some $800,000 gold (£80,000) in bonds in the United Kingdom. This company (with its subsidiary companies) have recently purchased many of the principal lighting and power plants in the State, and are promoting agriculture by means of electrical pumping for irrigation.

South Africa.—The "South African Mining Journal" of June 25 states that Mr. Howard Pim has obtained, on behalf of the Transvaal Hydraulic Power Synd. a licence for the installation and working of an electric generating station, at Tweefontein, district of Middelburg.

The station is to use small and second class coal from the Tweefontein colliery, and is to obtain its water from storage reservoirs on the Olifants River and the Zaaiwater and Piet Spruits. It is proposed to form a company with a nominal capital of £926,000 to take over the undertaking. Power will be taken from the new station for electro-chemical works to be established at Tweefontein for the manufacture of nitric acid, cyanide, calcium carbide, fertilisers and other chemicals.

Klerksdorp Council have adopted a scheme for electricity supply, estimated to cost £9,500. Duplicate generating plant is to be installed.

Turkey.—The Belgian Vice-Consul at Tripoli (Syria) states that Tripoli municipality are considering the question of the erection of an electric generating station for lighting purposes and the construction of electric tramways and a telephone system.

ELECTRICITY SUPPLY AND TRAMWAY ACCOUNTS.

Accrington.—The accounts of the electricity department for the year ended March show capital expenditure £74,989 (increase £3,345). The amount borrowed is £74,989, of which £54,888 is outstanding.

Income was £16,641, gross profit £7,416 (9·9 per cent. on the capital outlay). Interest and redemption required £5,469, leaving net profit £1,947, which (with a balance of £866 brought forward) has been appropriated as follows:—Depreciation and renewals £500, repayment of part of cost of 1890 Provisional Order £464, first instalment in repayment of deficiencies in previous years £140, cost of installations of wiring, meters, motors, economisers, pipework, paving and cost of Church Provisional Order, £1,709. The amount at credit of depreciation and renewals is £3,015. Units generated were 3,077,839. Private consumers took 1,779,795 (1,973,280), public lamps 37,574 (38,818) and tramways 1,063,299 (960,514). Working expenses were 0·768d. (0·673d.) per unit (including an increase of local rates of £599). The maximum supply demanded was 1,338 kw.

Bristol.—The accounts of the electricity department for the year to March 25 show capital expenditure £821,052 (increase £10,304), £798,108 has been borrowed, and the amount repaid and in redemption fund is £178,410.

Revenue was £79,572 (compared with £81,390), working and general expenses were £36,751 (£38,226), gross profit was £42,821 (£43,164), to which are added £2,346 refunded on adjustment of income tax and £97 transferred from redemption and sinking fund (No. 2) account. Dividends on stock, interest on loans, &c., required £22,082, repayment of capital £22,102, and £3,109 has been placed to reserve for renewals, the net result being a deficiency for the year of £2,030 (compared with £305). There is, however, a balance in hand from last account £6,230, so that £4,042 remains to carry forward. Units sold were 814,237 (increase 31,419). There are 3,388 consumers (increase 170), and the total connections are equivalent to 521,124 30 watt lamps (compared with 502,209). The total maximum demand was 5,729 kw. The metallic filament lamp has obviated the necessity of increased capital expenditure (except for connecting and supplying new consumers), but it has considerably reduced the revenue. Power connections increased by over 650 H.P. The load factor has fallen from 17·23 to 16·22. Costs have been slightly lowered, and it is believed the reduction in revenue due to the introduc-

Digitized by Google

tion of the metallic filament lamp has now reached its limit, and that an increased consumption may be looked for each year.

The report and accounts were adopted by the Council on Tuesday when Ald. PEARSON said he had no doubt he would in 1911 submit a better report. The present position was an abnormal one, brought about by a change which must ultimately be for the good of the undertaking. He quoted instances in which there had been great reductions in the amounts of the accounts of individual consumers. They had in the sinking fund or in the shape of machinery paid for out of revenue £216,981, and he thought it would be difficult to find any company carrying on business on similar lines that could say that in 15 years 25 per cent. of the total capital was in its own works or in the sinking fund.

Carlisle.—The accounts of the electricity department for the year to March last show capital expenditure £70,360 (increase £6,164). The oustanding loans are £53,915, including £3,241, the amount of loans fund overdrawn. The total amount of loans raised is £75,084.

Income was £12,852 and expenditure (including £52 insurance and £44 allowance for bad debts) £4,933. Gross profit was £7,919. Net profit was £3,057 (an increase of over £800). Units generated were 1,557,487 (increase 170,234), public lamps took 72,720 (75,721), private consumers (including traction) 1,226,277, the increase in the power and private lighting demands being 154,455 and 8,459 respectively, and the decrease in the traction demand 4,428.

The report of Mr. S. T. Allen (borough electrical engineer) states that Carlisle takes fourth place amongst local authorities' undertakings in regard to the proportion of gross profit to capital expended (11·77 per cent.). There have been no engine failures during the year, and the general supply has been maintained without interruption. Motors aggregating about 90 H.P. were connected during the year, and applications were received for about 600 H.P. The motors connected total over 250, with a total power of over 600 H.P. Connections to the mains increased during the year by 4,254 (equivalent) 30-watt lamps. There were put in at the works during the year a coal bunker, with coal-handling gear, automatic stokers to each boiler (not quite completed at end of financial year), superheaters, two boiler feed ranges re-erected in sight above the boilers, and a new steam turbine set. The last mentioned showed an improvement on the maker's guarantee figures. Fuel cost 0·24d. (compared with 0·30d.) per unit sold, total works costs were 0·56d. (0·70d.) and total, including rates and taxes, management and insurance, 0·87d. (1·04d.)

Chesterfield.—The accounts of the Corporation tramways department for the year ended March last show capital expenditure £69,575 (no increase). £70,500 has been borrowed and £6,800 repaid, besides a contribution of £1,600 towards the cost of the Corporation Tramways Improvement Act, 1904.

Revenue was £11,859, working expenses £7,402, sinking fund contribution, interest, &c., amounted to £4,529, the net surplus being £26. Passengers carried were 2,430,326, car miles run 281,096, and units of current used 374,823, equal to 1·3 units per car mile. Total revenue was 10·12d. (compared with 9·51d. in previous year). Total costs (including power) were 6·317 (exclusive of capital charges). Reserve fund stands at £3,653, or 5·17 per cent. on the total capital expenditure.

Manchester.—The accounts of the electricity department show capital expenditure £2,678,630, an increase of £111,924 during the past year. The loan debt stands at £1,970,112, the amount of loans redeemed by sinking fund being £617,133.

The income during the year ended March last was £374,479 (compared with £367,240 in previous year), and expenditure was £181,398 (against £184,039). £23,822 (£21,495) was placed to renewals suspense account and £169,258 (£161,706) carried to net revenue account. Interest required £69,311 (£67,966), sinking fund £82,168 (£75,913), and instalment of loan repaid £6,198 (£6,031). £183 (£403) has been placed to reserve and the net profit is £12,000 (as in previous year). This has been devoted to relief of rates. Units generated were 95,542,254 (88,766,232), private consumers took 42,886,223 (37,150,022), public lamps 144,696 (99,593) and traction 28,526,468 (29,675,249). The total maximum demand for lighting and power was 24,193 kw. (20,956 kw.) and for traction 9,592 kw. (10,162 kw.).

The report of the Electricity committee states that the Tudor battery scheme at Dickinson-street and Bloom-street stations is in successful operation and the Contraflo condensing plants have also been satisfactorily installed. The large extensions of steam plant and accessories at Stuart-street station have been brought to a satisfactory conclusion, substantial improvements in the h.-t. switchboards having been effected and the works in connection with obtaining an independent water supply for the station are almost complete. The net addition to mains during the year is 16 miles 1,242 yds. The efficiency of the distributing system was 82·02 per cent.

Stafford.—The accounts of the electricity department for the year ended March last show capital expenditure £32,500 (no increase during the year) and the loans outstanding amount to £23,137.

Revenue was £4,344, working and general expenses £1,865, gross profit £2,479 (compared with £2,465), and after meeting capital charges the net profit was £374, of which £341 has been placed to depreciation fund. Units generated were 509,016 (compared with 505,139 in previous year), private consumers took 381,375 (371,688) and the public lamps 8,635 (8,665). The number of (equivalent) 8 c.p. lamps connected is 25,496 and motors connected 74 (=346 H.P.). The total maximum demand was 280 kw. (against 295 kw.)

Tunbridge Wells.—The accounts of the electricity department for the year ended March show capital expenditure £88,250 (increase £3,887).

Revenue was £13,728, working and general expenses £8,649 and gross profit £5,079. Contributions to loans fund required £4,375 and mortgage loan £989; total £5,364. Units generated were 1,078,018; public lamps consumed 253,111 (estimated) and private consumers 578,025. The number of lamps connected is 70,681 (increase 3,824). The total maximum demand was 569 kw. (648 kw.).

The resident engineer (Mr. J. W. Beauchamp) states that since June, 1909, the department has been under fresh management. The steam turbine, ordered by the consulting engineer, and the mechanical stoker (now being supplemented by a second one) were put into use. Extensive repairs to the whole of the plant were carried out. A reduction in coal and oil amounting to nearly £700 was effected, this figure being taken after correction for decrease in units generated. A considerable falling off in lighting revenue was experienced as a result of increased use of metal filament lamps. The use of these lamps with or without transformers is practically universal here on all new work, and the price of 4¾d. per unit under these conditions makes competition with gas (at 2s. 7d. per 1,000) comparatively easy. Some installations have been put in on the "Stannos" system, and changes in meter and service charges have been made in order to reduce the first cost of installation to consumers. Metal filament lamps are used for street lighting, and the older type of open arc lamps are being replaced by high candle power metal filament lamps. The electric lighting of the schools of the borough is now receiving consideration.

TRADE NOTES AND NOTICES.

TENDERS INVITED.

Tenders are invited up to Sept. 7 for supply of battery material and glassware to the Postmaster-General's Department in QUEENSLAND. Tender forms and specifications from the Official Secretary in Great Britain of the Commonwealth of Australia, 72, Victoria-street, London, S.W. See also an advertisement.

Tenders are invited up to Aug. 30 for supply of telegraph and telephone material to the Postmaster-General's Department in VICTORIA. Tender forms and specifications from the office of the High Commissioner for the Commonwealth. See also an advertisement.

Tenders are invited for the supply of 3 tons 2 cwt. of bare h.d. copper cables to the Corporation of MELBOURNE (Australia). Specifications form of tender, &c., from the Agents of the City Council, Messrs. McIlwraith, McEacharn & Co., Proprietary (Ltd.), Billiter-square-buildings, London, E.C., to whom tenders by noon, Aug. 16. See also an advertisement.

NEWPORT (Mon.) Electricity and Tramways committee invite tenders for supply of carbon filament electric lamps, radiator lamps (British made), flame arc lamp carbons for Excello and Oliver type lamps, and a.-c. and d.-c. two-rate and prepayment meters, during the ensuing 12 months. Specification and schedule from the borough electrical engineer and tramway manager, Mr. H. Collings Bishop, M.I.E.E. Tenders to the Town Clerk, Town Hall, Newport, Mon., by first post Aug. 15.

LONDON County Council invite tenders for the wiring and fitting for electric lighting of the second section of the central car repair depot, Woolwich-road. Specifications, &c., from the Clerk of the Council, County Hall, Spring-gardens, S.W. Tenders by 11 a.m. Tuesday, Aug. 30.

MANCHESTER Electricity committee want tenders by noon Aug. 2 for supply and erection of induced draught plant at Bloom-street generating station. Specifications, &c., from Mr. F. E. Hughes, Town Hall, Manchester.

CHELMSFORD Education committee want tenders by Aug. 31 for electric light wiring at Trinity-road school. Forms, &c., from Mr. W. H. Pertwee, London-road, Chelmsford.

Tenders are wanted by noon Aug. 2 for the electric lighting of the Royal Hospital for Incurables, DONNYBROOK, Dublin. Specification from Mr. T. Tomlinson, 15, Beresford-place, Dublin.

EDINBURGH School Board want tenders by Aug. 2 for the electric lighting of the Royal High School. Specifications from Mr. Geo. Thomson, 11, Randolph-place, Edinburgh.

Tenders will be received by the Minister of Telegraphs, G.P.O., WELLINGTON (N.Z.), until noon Dec. 15 for supply and erection of installations of wireless telegraphy at or near (1) Doubtless Bay, (2) Gisborne, (3) Cape Farewell, (4) Sumner, near Christchurch, and (5) Bluff. Specifications, &c., from 13, Victoria-street, London, S.W.

The Deputy Postmaster-General, BRISBANE, will receive tenders until noon Sept. 7 for supply of glass cells, corks and tubes and

Digitized by Google

porous cups for batteries, battery material, chemicals, &c. Specifications, &c., from the High Commissioner for the Australian Commonwealth, London. Local representation is necessary.

The Deputy Postmaster-General, MELBOURNE (Victoria), will receive tenders until 3 p.m. Aug. 30 for supply of electrical sundries, insulators, wire and sulphate of magnesia. Local representation necessary. Further particulars from 72, Victoria-street, London, S.W.

The SECRETARY OF STATE FOR INDIA requires tenders by 2 p.m. Aug. 3 for supply of overhead floating staging and electrically-driven water supply pumps. Conditions, &c., from the Director-General of Stores, India Office.

The Turkish Ministry of Commerce and Public Works want tenders by Oct. 28 (Nov. 10) for a concession for the construction and working of electric tramways in CONSTANTINOPLE and suburbs. A deposit of £13,500 (sterling) is required with each tender. Local representation is essential. Copy of specification (in French) may be seen at 73, Basinghall-street, London, E.C.

Tenders will be received at the French Government Telegraph Department, Rue de Grenelle, PARIS, on Aug. 6 for supply of 150 tons of 2 mm. and 100 tons of 3 mm. bi-metallic wire.

COPENHAGEN Lighting Department want tenders by noon Aug. 2 for the supply of electricity meters and by noon Aug. 4 for 11 months' supply of cables for their d.c. system. Specifications, &c. (in Danish), may be seen at 73, Basinghall-street, London, E.C.

The Italian State Railways Administration, 16, Via Ludovici, ROME, want tenders by Aug. 22 for supply of 584,000 common carbons for arc lamps. Only firms on list kept by administration are generally allowed to tender. Local representation is practically necessary.

Tenders will be received at Spezia and Venice until 11 a.m. Aug. 13 for supply of electric wires and cables to the ITALIAN STATE RAILWAYS Administration. Specification (in Italian) at 73, Basinghall-street, London, E.C. Only firms on Government list are usually allowed to tender.

TENDERS RECEIVED AND ACCEPTED.

London County Council have accepted the following tenders:—

Dick, Kerr & Co. (lowest tender), for platelaying of tramways from Battersea Park-road to Kings-road, Chelsea, £21,629. 12s. 2d. (Five tenders were received; highest £23,783. 10s. 4d. Chief engineer's estimate, £22,353. 11s.)

Ernest Scott & Mountain (lowest) for supply of electric winch for Forest Hill substation, £135. 1s. 6d. (Five tenders received; highest £202. Chief officer's estimate, £143.)

F. Mountford (Ltd.) (lowest) for 266 standard door locks for 133 sets of draught screens on electric cars, 7s. each, less 2½ per cent. Total £90. 15s. 6d. (Six tenders received; highest 10s. 6d., less 2½ per cent. Chief officer's estimate £95.)

For deal paving blocks at per 1,000: Burt, Boulton & Haywood (£6. 2s. 6d. to £6. 17s. 9d.), Improved Wood Pavement Co. £6. 2s. 6d. to £6. 18s.)

For Jarrah wood blocks at per 1,000: Millar's Karri & Jarrah Co. (£5. 10s. 6d. to £10. 18s. 3d.), and Wm. Griffiths & Co. (£5. 9s. to £10. 16s.)

Stepney (London) Council have accepted the tenders of the General Electric Co. for a power switchboard and of W. White & Co. for a lighting switchboard. The following were the tenderers and their amounts for the power and lighting boards respectively: Edison & Swan Co., £123. 9s. and £12; Kelvin & James White (informal), £130. 2s. and £21. 8s.; General Electric Co., £142 and £22; Elliott Bros., £144. 10s. and £22. 5s.; W. White & Co., £154 and £16. A. W. Penrose & Co. (both boards), £164; Crompton & Co. (both boards), £192.

Bermondsey (London) Council has accepted the following tenders:—

Loudon Bros., lathe, £45, and "champion" forge, £6. 7s. 6d.; Nelson Bros., pillar drilling machine, £29. 10s.; J. Howden & Co., spare piston block complete with rings, £21.

Leicester Corporation have accepted the tenders of Willans & Robinson for a steam turbine and Siemens generator, £7,353; Yates & Thom for steam-raising plant at £2,686; Bowles & Son for extension of power station, £3,118; and Cross & Cross for steel roof trusses, £150. 13s. 8d.

Fulham (London) Council have accepted the tender of the Electrical Co. for 150 electricity meters (3, 5 and 10 ampere at £1 each, 25 ampere £1. 3s., 50 ampere £1. 4s., 75 ampere £1. 9s., 100 ampere £1. 11s. 6d.); total £153. 10s.

Littleborough Council have accepted the tender of W. T. Henley's Co. for l.t. feeders and distributors and the erection of a transformer kiosk and supply of transformers and sub-station switchgear.

Hornsey Education committee have accepted the tender of F Bevan & Co. for the wiring, &c., for the electric light of Stroud Green school at £224. 17s. 2d.

Southend Corporation have accepted the tenders of the Jandus Arc Lamp Co. for 13 arc lamps at £104. 5s., and of Siemens Bros. Dynamo Works for an ampere-meter.

Hammersmith (London) Council have accepted the tender of the Standard Cable Co. for 2,500 yds. of 0·025 l.t. service cable at £181.

BUSINESS NOTICES.

John Allen Plumb and Fredk. Wm. Horsfield, electrical engineers, 64, Newman-street, W., and 62, Argyle-road, Tottenham, N., London, have dissolved partnership.

Dr. Alb. Lessing, of the Carbon Works, Nürnberg, announces that, in order to give the fullest technical attention to inquiries, he has withdrawn his London agency for the electrodes department, and invites those interested to communicate direct with the head office at Nürnberg.

We are informed that Mr. Henry W. Bowden and Mr. William Boby have entered into partnership as consulting engineers at Salisbury House, London, E.C. Mr. Bowden retains his offices at 30, Craven-street, Strand, W.C., for the present.

Messrs. Siemens Bros. Dynamo Works announce that their works at Tyssen-street, Dalston, London, N.E., will be closed during August Bank Holiday week, and that only urgent business can be attended to.

Messrs. Everett, Edgcumbe & Co. intimate that their works at Hendon will be closed during the whole of next week, and that urgent matters should be addressed to 117, Victoria-street, Westminster, S.W. Goods can only be received at the works.

The partnership between G. H. Bowden, F. C. Anderson and C. A. Atchlay, electrical engineers, London and Glasgow, has been dissolved.

Plant for Sale.—Two gas driven alternator sets of 250 kw. each are advertised for sale.

Dewsbury Corporation invite offers for one steam engine with two dynamos coupled to it, and also switchboard panel and resistances. The engine is of Willans & Robinson's make, two F compound 450 revs. per min. and built for 150 lb. pressure at stop valve. The dynamos are of Crompton's make, of 15 kw. each, and work at d.c. pressure of 220-250 volts. Can be seen running. Particulars from the borough electrical engineer, Mr. R. H. Campion. Offers to the Chairman, Electricity and Tramways committee, 93, Bradford-road, Dewsbury. See also an advertisement.

Patents Development.—The proprietors of patents No. 18,408/1906, for "Improvements in electric insulators for h.-t. conductors," and No. 23,878/1900 for "Improvements in process of and mechanism for separation of conductors from non-conductors," desire to enter into arrangements for exploiting same in this country. Communications to Messrs. Haseltine, Lake & Co., 7 and 8, Southampton buildings, London, W.C.

Old Type Arc Lamps.—Messrs. H. G. Mayer & Co., 67, Aldersgate-street, London, invite those who are thinking of scrapping their old open type arc lamps to apply for samples of their new Plania flame carbons suitable for these lamps.

Childs' Lifts.—Messrs. J. G. Childs & Co., of Willesden, have recently been making a large number of electrically worked lifts. Recent orders for this class of apparatus include 15 lifts for the Admiralty, of which nine are installed on H.M.S. "Lion" and six on H.M.S. "Orion." The lifts are controlled by push button apparatus, and are designed for both passenger and goods service. They work up and down the ventilating shafts. The same firm has also installed a 15 cwt. goods lift for the Lancashire & Yorkshire Railway at Waterloo Station, Liverpool, and two 1-ton goods lifts for the Great Western and Midland Railway Joint Committee at Worcester station. We understand that this firm are opening new works to cope with the increasing business of the lift and wind turbine departments.

Electrical Heating of Rooms.—Mr. S. L. R. Price forwards a pamphlet dealing with a system of electrical heating which is specially intended for use in warming glasshouses and other similar places. The method adopted is that of surrounding the area to be dealt with by a series of electrical tube heaters, or in drawing air over one or more heaters and circulating by a fan. In this way, it is claimed, an even heat is obtained, while the advantages of cheapness, security and speed are also secured. It is said to require ½ watt-hour to raise 1 cubic ft. of air 5° F.

Tuition by Correspondence.—From the Tutorial Press (Ltd.), Cambridge and London, we have received a copy of the Matriculation Directory (No. 55, June, 1910), of the University Correspondence College. On previous occasions we have referred to the good work done by this college and its staff of teachers. The Directory, which has been carefully prepared and edited, gives particulars of the various courses of instruction for the examinations of the University of London, and there are useful articles on text-books, courses of reading, &c. The questions set at the June matriculation examination of the University of

Digitized by Google

London, together with model solutions, are given. Those who are desirous of graduating at the University of London should procure a copy. The published price is 1s. net.

Electricity Supply at Tunbridge Wells.—We have received from the Tunbridge Wells Electric Supply Department a well-illustrated pamphlet showing the uses to which electricity can be put. This is evidently intended for distribution amongst both actual and prospective consumers. It begins with an interesting historical description of the Tunbridge Wells works, and goes on to deal with the advantages of electric lighting by metal filament lamps, while details of new electric heating apparatus and the economies which may be effected by using this agent for both heating and cooking are also given. Modern shop-lighting by arc lamps and the uses of electricity in the garage are also dealt with.

Aberdeen and Industrial Development.—The Industrial Development committee of Aberdeen Corporation have issued an elegant pamphlet, containing effective views of the docks, Castlegate, King's College and the Market Cross, and a plan of the city and burgh of Aberdeen, and giving some information as to the history of the town, statistics relating to the municipal departments (electricity supply, tramway, gas, water, sewerage and cleansing), the facilities for transport to and from Aberdeen, the chief industries, wages of artisans, house rents, education, building sites, &c. Copies can be obtained from the Town Clerk.

CATALOGUES, &c.

Ball Bearings.—We have received from the Stefko Ball Bearing Co. a catalogue dealing with these bearings, the invention of a Swedish engineer, Mr. Sven, of Wingquist. These bearings have only lately been introduced into this country.

Electric Fittings.—Mr. G. Braulik has a new price list ready of c.i. and water-tight fittings for electrical work, &c.

Tantalum Lamps.—Messrs. Siemens Bros. Dynamo Works inform us that they are now placing on the market a tantalum lamp in a tubular bulb, suitable for single or series burning at 100 and 130 volts. The candle-power of this lamp is 25, and its price is 3s.

Wright & Wood Motors.—Messrs. Wright & Wood, Halifax, send us a copy of their list dealing with motor-generators, rotary-transformers and converters. These are made in a number of sizes and types, especial attention being paid to the use of these machines for biograph work, battery charging, X-ray work and boosting.

Electrical Accessories.—Among the firms who make it theirbusiness to supply electrical accessories of all kinds to the trade one of the most important is certainly the Sun Electrical Co. Their latest catalogue will, therefore, be of special interest to our readers, and we should recommend all those whose business it is to purchase electrical apparatus in large quantities to provide themselves with a copy. The first part deals especially with electric lighting accessories, including ceiling roses, wall plugs and small switches. Such apparatus as cutouts, ball and counter-weight fittings and accessories for wiring work are also described. The company expect to issue section 2 of this catalogue, which deals with distribution and switchboards, in due course.

Galvanic Batteries.—Messrs. Siemens Bros. & Co. send us a copy of a reprint dealing with the methods of manufacture employed at their Woolwich works in the making of dry cells. They will be pleased to send a copy of this fully illustrated description of a large variety of their batteries to anyone who cares to apply for it.

Silent Chains and Sprockets.—We have received from Messrs. Hans Renold (Ltd.) a new catalogue dealing with their new patent silent chains and sprockets. A new feature in this is a section dealing with the development of the Renold silent chain. Additions and alterations have been made, and the catalogue is now quite up-to-date.

Bolts and Nuts.—Messrs. T. W. Lench (Ltd.), of Fenchurch-street, have sent us a copy of a catalogue dealing with various bolts and nuts made by them. Black, bright and brass varieties are illustrated. We should recommend the study of this catalogue to anyone requiring bolts and nuts in large quantities.

Electrical Accessories.—The Victoria Electrical Works, od Upper Thames-street, have just issued a new illustrated price list, of which they have sent us a copy. In it are to be found illustrated details of all the various accessories which the wiring contractor has to use inthe course of his work.

Duddell Oscillographs.—In a note on this subject which appeared on p. 626 of last week's issue we mentioned that the Cambridge Scientific Instrument Co. were supplying one of these instruments to "a large firm of cable makers in Australia." This should have read "in Austria." In our opinion this makes the matter even more satisfactory.

BANKRUPTCIES, LIQUIDATIONS, &c.

Harold Bristow, electrician, &c., 368, Hessle-road, Hull, has been adjudicated bankrupt.

Walter Lee Grimsley, electrician, Eureka Motor Works, Shelley-road, Boscombe, Hants., has been adjudicated bankrupt. First meeting of creditors July 30 at Arcade-chambers, Bournemouth, and public examination Aug. 26 at the Town Hall, Poole.

A dividend is to be paid to creditors of Herbt. John Burdett, electrical engineer and contractor, 16, Regent-street, Rugby, and 32, Earl-street, Coventry. Claims to Mr. A. Cripwell, 12, Cherry-street, Birmingham, by Aug. 10.

Dividends are to be paid to creditors of Alfd. Ernest Felgate and Wm. Storey, electrical engineers, 10, Victoria-street, Reading, and also in respect of the separate estate of A. E. Felgate. Claims to Mr. B. P. Allnatt, 2, Forbury, Reading, by Aug. 5.

An application for the discharge of Hy. K. P. Barham (trading as the South of England Electrical Engineering Co.), 60, Fratton, Portsmouth, will be heard on Oct. 13 at the Court House, St. Thomas's-street, Portsmouth.

PATENT RECORD.

APPLICATIONS FOR PATENTS.

*Note.—The undermentioned Applications (except those marked †) are not open to public inspection until after acceptance of Complete Specifications. Those marked * are open for inspection 12 months after the date attached to them, if they have not been published previously in the ordinary course. COMPANIES' MEETINGS AND REPORTS.

Direct United States Cable Co. (Ltd.)

The sixty-sixth ordinary general meeting was held on Tuesday, under the presidency of Mr. E. M. UNDERDOWN, K.C.

The SECRETARY (Mr. William Miles) having read the notice calling the meeting and the auditors' report,

The CHAIRMAN said: The revenue for the six months to June 30 last, after deducting outpayments, amounted in round figures to £58,556, the working and other expenses, including income tax, but exclusive of the cost of maintenance of cables, absorbs £25,277, leaving a balance of £33,279 as net profit, which, with £6,859 brought forward from the previous half-year, gives a total of £40,138. This sum has been appropriated as follows: An interim dividend of 4s. per share to March 31 last required £12,142, and the proposed final dividend of 4s. per share, with a bonus of 2s. per share to June 30 will require £18,213; we have transferred £5,000 to the reserve fund, and we carry forward the balance of £4,783. Compared with the corresponding six months of 1909, the revenue shows an increase—not very large, but, at all events, very satisfactory—of £2,112. The working expenses are within £150 of the total of such expenses for the corresponding half-year of 1909. The reserve account has been credited with £9,772 from interest on investments, £137 profit on the sale of securities, and £5,000 transferred from revenue, as I have previously informed you. The amount debited for maintenance of cables during the six months was exceptionally small. We were fortunate in not having any serious interruptions to our cable at all, and the amount was only £3,584, as compared with £13,857 for the half-year to June, 1909. It is always gratifying not to have any interruption during a particular six months, but, of course, we cannot assume that we shall not have interruptions in our shorter cables from time to time. After charging the before-mentioned amount, the balance of the reserve fund account stands at £533,024, as compared with £510,267 this time last year, or an increase of £22,757 during the year. The investments representing this fund appear in the balance-sheet at £523,878, after allowing for the provision of £40,000 made three years ago on account of market depreciation, and it is satisfactory to be able to state that the market value of the securities on June 30 last amounted to £533,856, or £10,000 in excess of the balance-sheet figure, showing that we are recovering to a certain extent what we had to provide against. These accounts are for the second half of our financial year, so, summarising them, the revenue for the year amounted to £118,894, as compared with £112,780 in 1909, and the expenditure to £50,567, as compared with £50,400, leaving a balance of £68,327, which has been dealt with as follows: We have paid in dividends £54,639, as compared with £51,603 in the previous year, and have placed to reserve £12,500, as compared with £10,000. These two items amount to £67,139, and adding the increased balance in hand as compared with that at June, 1909, of £1,188, the above amount of £68,327 is arrived at. Now, the last time I had the pleasure of addressing you I informed you that we had in contemplation the shifting of the cable to a point in Newfoundland which you may, perhaps, recognise under the name of Harbour Grace. All the arrangements have been made for carrying out that work, and we trust that in the ensuing month the matter will be carried through. Naturally a good deal of negotiation was necessary in order to place us in a position to carry this through, and the *modus operandi* was that our manager, Mr. Fenn, went to Newfoundland, and on behalf of the company he has purchased land and buildings at Harbour Grace with a frontage to the sea suitable for the landing of the cable. These negotiations have been carried out on what we consider very advantageous terms. We have also acquired the landing rights for our cable, and various concessions from the Government and the Municipality, and a boat is now on its way to Newfoundland with the first consignment of cable and equipment for the new station. With regard to the position of the Direct Company generally, you have doubtless heard a great many statements with respect to alterations in rates and so on, but at present I need not trouble you with them, because no distinct arrangement has been carried out. Now, with respect to this satisfactory state of things, I said, in answer to a question on the last occasion, that as soon as our reserve fund had arrived or was maintained at a figure we considered necessary, we should give the shareholders the benefit of a certain portion of that amount. I must say that, in my opinion, for many reasons which it is not necessary for me to allude to, it is necessary that we should keep up this reserve fund, which so much strengthens our position. At the same time, we hope that inasmuch as the length of the main Atlantic cable will be somewhat shortened, the reserve may be regarded as favourable when compared with the expense of laying a new main Atlantic cable. The repairs have been paid for from time to time out of the reserve fund, and there is very little to remark with respect to them. I trust that we shall be able to continue to give you a satisfactory bonus. I referred at the last meeting to the sad death of our late secretary and manager, Mr. Finnis, and I also mentioned that we had ceased to keep up the combination in one officer of those two positions. We have now an experienced manager, who is thoroughly acquainted with the work on the other side as well as with the work on this side, and the late secretary has been succeeded by Mr. Miles, with whom we are entirely satisfied both in regard to the manner in which the business is now carried on, and the way in which the general staff arrangements are carried out. I should also speak favourably with regard to the staff in general. I now move the adoption of the report and accounts and the declaration of the dividends and bonus set out therein.

Sir JAMES PENDER, Bart., seconded the motion.

Answering Mr. C. R. Fry on the subject of the recent rumours reported in the financial journals,

The CHAIRMAN said: I did not allude to these so-called negotiations because I had nothing to tell you with respect to them. There have been very long reports in the financial papers of all sorts of things which are said to have taken place. Those things have not taken place; the statements made are not correct. Unofficial conversations have taken place with respect to the large company you spoke of, which, no doubt, is a very powerful organisation for the introduction and development of telephones in the United States. Our ally is the Western Union, which is a big telegraph company. It has also been said that the telephone company mentioned has control of our partner. Of that I know nothing. If control means a large majority, I do not think that is so; but you will, I am sure, appreciate what I say—that conversations of this kind published in the papers with more or less incorrectness are not things which I could profitably discuss with you. In fact, the position I take is that with this company no negotiations, properly so called, have taken place, and seeing the strong position we are in, with our good business and our satisfactory reserve fund, I think that propositions, if they were made, which would in any way affect our entity or position, would require to be examined with the utmost care. I do not think that anything is likely to be determined in a very short time, but naturally anything that is done must be done with the approval of this company, and what is done by this company must be done with the approval of its shareholders.

The motion was then carried unanimously. The retiring director, the Hon. T. H. A. E. Cochrane and Mr. John Varley, were re-elected, as were the retiring auditors, and a hearty vote of thanks to the chairman, directors and staff brought the meeting to a close.

City & South London Railway Co.

The fifty-second ordinary general meeting was held on Tuesday. The Right Hon. C. B. STUART-WORTLEY, K.C., M.P., presided.

The SECRETARY (Mr. W. F. Knight) read the notice convening the meeting, and also the auditors' report.

The CHAIRMAN said: Gentlemen, the main facts the half-year's accounts bring out are that our gross receipts are less by £731 and our expenses are more by £2,237, so we have a net revenue diminished by £2,968. Increased charges for interest on money borrowed, with other things, bring the diminished net revenue down to a total balance available for distribution less by £3,477. We, therefore, recommend a dividend at the rate of £1. 5s. per cent. instead of the £1. 15s. a year ago, but we carry forward £1,535 against £1,412. Various causes have contributed to our loss of traffic. We have carried close on 11½ millions of passengers in the half-year, a greater number than ever before in our history, and a greater number by close on 270,000 or 2·4 per cent. than a year ago, when the reduced fares had not come into operation. These reduced fares were, as regards through fares, forced upon us by the need of continuing to act in harmony with the policy of other tube railways with which we are in physical connection as well as organically allied by the common interest which arises from the fact that we and they are feeders each to the other. In face of the increased number of passengers carried it is impossible to say that our service is losing in popularity with the public. But we do not believe that at the old fares we should have got the new patronage, or even kept all our old customers. We have run 30,579 more train-miles than a year ago. Of these increased train-miles the new Sunday traffic accounts for 13,486 train-miles, or an increase of 44 per cent. The rest of the increase is due to our having continued in spring and summer the higher number of trains per day which ordinarily were regarded as necessary in winter alone. This we have done partly under the pressure of the Board of Trade in the matter of alleged overcrowding, and partly under the stress of competition to attract fresh traffic. This increased number of train-miles run has had the effect of reducing the receipts per train from a fraction over 18s. 3d. to a fraction over 17s. 4d., and the receipts per train-mile from 2s. 5·93d. to 2s. 4·37d. On the other hand, the total expenses per train-mile are up from 1s. 2·11d. to 1s. 2·25d. This increase is partly due to locomotive charges, which are up from 4·52d. per train-mile to 4·70d. It is, however, not due to traffic expenses, excluding lifts, for these are down from 4·37d. to 4·32d. Lift expenses per train-mile are up from 1·76d. to 1·84d. This is partly due to increased expenditure on wire ropes, which need not be expected to recur every half-year. Expenses generally have been added to by an

Digitized by Google

increased weight of coal consumed of 544 tons, at an increased cost of £585, to which a rise in price has contributed at the average rate of 5½d. per ton.

On the subject of the increase of wages I may say a word. You doubtless have seen that, under what is known as the Conciliation Boards Agreement come to in 1907, most of the railway companies have, after discussion with their men at Conciliation Boards, and with or without recourse to arbitration afterwards, granted certain increases of pay to their men. This company and its employés are in one respect differently placed to others. With us the number of men and of classes of men are, comparatively speaking, so small, and the subordinate and intermediate functionaries so few, that the men have, and always have had, access to the supreme executive for the purpose of discussing grievances or anything else, with a freedom and readiness that is seldom found possible in the case of the much larger numbers employed by the great railways. And such has been the good sense and good feeling with which those discussions have been carried on, on the one hand by fully representative deputations of our men, and on the other hand by our excellent and popular general manager, that we are able to announce that an agreement has been arrived at, which gives certain of the men advantages, either in time or in money or in both. In return the men waive the institution of a conciliation board, and allow us to report to the Board of Trade that at present none has been found necessary. This agreement holds good till Dec. 31, 1914.

On the quinquennial re-valuation of ratable property in the metropolis we still have discussions pending with local authorities. These new valuations take effect from April, 1911. We believe we have greatly improved the condition of the atmosphere at our Clapham Common station by using an electrical apparatus which ozonises the air. Already our staff there tell us they have found great improvement in the atmosphere, and it is to be hoped that the public will notice and appreciate the like good effects. I now move the adoption of the report and accounts.

Mr. CHARLES SEYMOUR GRENFELL seconded the resolution.

Col. PERRY said he would like to suggest that the title or name of their railway be changed to "The North & South London Railway," instead of "The City & South London Railway." When the Manchester, Sheffield & Lincolnshire Railway came to London they did not retain their old designation, but called themselves the Great Central. Many people were still unaware that the City & South London Railway has any line to the north of the City. He therefore moved that this change of title be made

Mr. PORTER suggested the closing of two or three of the stations, thereby saving expense.

The CHAIRMAN said that the closing of three stations would be a serious matter. They had considered the question of closing City-road station, but there had since been some new places of business opened, and the traffic had a little improved.

A resolution approving the dividends was then carried.

Referring to the suggested change of name, the CHAIRMAN said: Our title, our statutory title, does not exactly describe what our railway is, but we have done all we can by circulating millions of maps and by illuminated electric signs and other forms of advertising, to inform the public that we run to Euston and that we give the public an excellent means of access to and from the City and King's Cross and Euston. The directors will take the matter into their consideration.

A hearty vote of thanks to the chairman, directors, officers and staff brought the proceedings to a close.

Crompton & Co. (Ltd.)

At the meeting yesterday (Thursday) the Chairman, Mr. JOHN TROTTER said that delay on the part of the building contractors had prolonged by a year the completion of an important contract in Madras, which had resulted in large additional and quite unexpected expenditure. However, the whole of the work had now been taken over and the contract might be said to be at an end. Loans from bankers had been considerably reduced, as had also the amount outstanding to sundry creditors. It was not satisfactory to go on trading with permanent loans from the bankers. Their liabilities had now been further reduced. The item to bankers was below £40,000, and the trade creditors item had been brought very much down. Their holding in the Electric Supply Corpn. had been reduced from £42,750 to £24,000 this year. These shares represented the price obtained by the Company for the Chelmsford electric lighting undertaking. Their holding in the Electric Supply Corpn. was higher than they considered the Company, as a manufacturing concern, was entitled to maintain. The profits of the Electric Supply Corpn. continued to increase, and the directors felt that in course of time there would be no difficulty in disposing of the remaining shares at satisfactory prices.

The £23,000 odd, which represented the loss carried forward, was a deplorable result, which, however, it would have been hard to avoid seeing that the gross profit was reduced from £60,500 to £31,826. The expenses at the works and head offices were £3,226 less than in the previous year, and in two years they had reduced expenses by £5,000. There seemed no apparent reason why prices should rise materially in the near future. Their only course was to increase sales and improve designs, and hope for some slight increase in market prices. There was every hope that some recent improvements in the designs of dynamos and motors would enable them to secure an increased amount of business, and as the designs admitted of economy in manufacture, they leave a better margin of profit. Their works were amongst the most modern of their kind, and he thought the cost of manufacture was as low at Chelmsford as anywhere in the country. He was glad to say that since Jan. 1 there was a distinct improvement in the value of colonial and foreign orders. Col. Crompton, although entitled to fees as consulting engineer, had asked him (the Chairman) to announce that in future he would forego these fees unless there was any special business to be entrusted in his hands.

Col. R. E. B. CROMPTON, C.B., said the person most hit by the adverse result they had sustained was himself. He brought a very large sum into the business, had added to his holding from time to time, and had never decreased it. The electric business in England was suffering along with the whole industrial world, and he did not think that their particular firm was suffering more or less than other well managed firms. They had had in a year when the output of the works was insufficient to cover expenses heavy and unforseen losses, for which no one in the Company could be blamed. Who could have forseen such a miscarriage of justice as took place in their lawsuit? The interpretation of a few words had cost the Company about £7,000. He agreed with the Chairman in not thinking that a substantial rise in prices was likely, but the works staff, in whose opinion he had the greatest faith, told him that if prices got no worse and the volume of orders got larger, they could again turn the corner and pay dividends. Nothing but prudence, patience, cutting down of expenses, and unremitting attention to everything that could secure increased sale of goods would avail them in returning to the dividend paying stage, and the board had appreciated this for a long time past.

Mr. G. BUTLER PAUL said he should like to offer their thanks and sympathy to the chairman and directors. The time must have been am exceedingly anxious and trying one, and it would be a satisfaction for tham to know that every shareholder present sympathised with them and thanked them for their attention to the business.

The CHAIRMAN said they much appreciated these remarks.

National Telephone Co. (Ltd.)

The forty-sixth ordinary general meeting of the shareholders of this Company was held yesterday at Hamilton House, Victoria Embankment, Mr. GEORGE FRANKLIN in the chair.

The SECRETARY (Mr. Albert Anns), having read the notice convening the meeting and the auditors' report,

The CHAIRMAN, in the course of his address, said: Ladies and gentlemen, I do not anticipate having to occupy very much time this afternoon, but there are a few points in regard to the report and accounts, as well as to the position of the Company generally, that I think the shareholders would like to have some information upon. First of all, with regard to the income accrued in respect of the business of the half-year, this year it has increased from £1,549,136 to £1,677,587, being an increase of £128,452 in the half-year—that is, this half-year as compared with the corresponding period of 1909. Then we come to the first deduction, the first tax, and that is the Postmaster-General's claim upon us, which is £161,529, as compared with £149,127, or an increase of £12,403, making the total sum which has been paid to the Postmaster-General for this tax upon this industry—for which he has rendered no service and done nothing at all—£3,295,434 of the shareholders' money. We next come to the net income, which amounts to £1,516,058, as compared with £1,408,008. That is an increase in the half-year of £116,049. The working expenses have increased from £890,798 last year to £974,757 this year, or an increase of £83,959. Then we come to the net result for the half-year, and we find that we have £541,300, as compared with £509,210, or an increase over the corresponding half-year of £32,090.

The administration and management expenses, office salaries and charges, operators' wages, &c., amount to £400,811, compared with £389,225, an increase of £11,586. This is more than accounted for by the increase in the operator's wages, which for several years have shown a tendency to rise, due first to the employment of more operators to cope with the increased business, and secondly to the fact that there has been a larger number of operators in the higher ranges or scale of pay. The maintenance and renewal of lines and instruments and depreciation allowances amounted during the half-year to £362,299, as compared with £316,049. That shows an increase of £46,250. Included in that expenditure is a sum which we show separately as an item for repairing damage caused by snowstorms, amounting to £20,331. That compares with about £7,000 in the corresponding half of last year, but apart from that increase in the snowstorm expenses, there is a large increase of between £30,000 and £40,000 in the maintenance and renewal of the Company's plant, and this large increase in maintenance may, I think, be accepted as an indication of the Company's determination, even at a present sacrifice, to maintain a high point of efficiency in the Company's plant and system. This policy has the advantage of enabling the Postmaster-General to acquire not merely our fine organisation and efficient staff, which he will get for nothing, but a plant and equipment fully maintained and in sound working condition, for which the Company will require payment. The sum of £125,970 which appears in the item Debtors for outstanding rentals, requires a word of explanation. We are dealing with five months of actual trade up to May 31, and one month of estimated trade, and that one month's figures are included in the debtor and credit balances in the June half-year in order that we might have our meeting before the holidays and distribute our dividend somewhat earlier.

The reserve fund will amount to no less a sum than £3,705,127. I have often explained at these meetings that that is the sum which is set aside as an insurance to provide for any possible diminution there might be in the Company's capital as a result of the valuation to be placed upon the Company's assets upon the sale to the Postmaster-General, and it must be satisfactory to the shareholders to be as far as possible

Digitized by Google

secured against contingencies. Therefore I hope the shareholders will be satisfied with the view which the Directors take when they say they feel that it is essential, even at this late period of the business, to try and make the position of the Company in every way as strong as possible before it enters upon the arbitration or the dispute, if there be a dispute, or I will put it in another way—before it enters upon the Unknown. None of us can tell what will result from the steps which are being taken to have a value put upon our plant, and no one can tell what will be the price, or anything near the price, which the Postmaster-General may be expected to pay. Therefore the shareholders have got to look at it in this way. They have to have confidence in their board, which they have always shown in the past, and, secondly, they have to feel that the board and the company are in a stronger position by reason of having this large increase and addition to the reserve fund. I do not think I can leave the accounts without making a remark on the result of the adoption a few years ago by the company of the system of payment according to user, known as the measured rate. The adoption of this system caused quite a little excitement and opposition from chambers of commerce and other parties, on the ground that the company's scale of charges would prove a heavy burden on those using that system. How unfounded and groundless those fears were is proved by the fact that at the present time the company have in the provinces about 124,000 stations based on this measured rate system, producing to the company in annual subscriptions or revenues an average annual income of £5. 12s. 8d. for the use of a telephone station for a year, and that is the average income per station from this system. It must be a boon to have a telephone at that moderate figure, and this method of charge has become a boon to the small user, because no unlimited or other method could give to the user the use of the telephone at such a rate, and the small user is an advantage to the telephone system, because, obviously, the larger your telephone system is, the greater its use is to those who are already subscribing to it. This huge business, with 16 millions of capital, has been built up in spite of the most vigorous efforts which have been made from time to time to smother it, and in the face of the greatest possible difficulties, and it is satisfactory to know that here to-day, as compared with any other country in Europe, with the exception of Germany, we are at the head of affairs in regard to the number of instruments per population, and considering our difficulties, that is a fairly satisfactory position. (Cheers.) I mentioned at the last half-yearly meeting that in the absence of the agreement with the Postmaster-General as to the value of the company's assets such value will have to be determined by arbitration, and that the company's officers were engaged in the preparations necessary for the inventory upon which the company's claim might be founded. Since that time the work has still continued, and the preparations are still proceeding. I observe that the Postmaster-General, in speaking in the House of Commons the other evening on the Post Office estimates, stated that he had very small hope that the purchase of this company could be settled otherwise than by arbitration. If this be so, as it probably is, the board have confidence in the case which they will be able to put before the arbitrator, and whilst in the public interest they will always be ready to co-operate with the Postmaster-General as far as possible, the shareholders may rest assured that the board will strongly guard the interests committed to their care. I beg now to move that the report and accounts be received and adopted, and that the dividends as recommended in it be paid.

The VICE-PRESIDENT (Mr. Samuel Herrick Sands) seconded the motion, which was at once carried unanimously.

The retiring directors and auditors were re-elected, and the proceedings closed with a vote of thanks to the chairman.

ANGLO-AMERICAN TELEGRAPH CO. (LTD.)—The total receipts from Jan. 1 to June 30, including £1,894. 1s. 8d. brought forward, amounted to £208,949. 15s. 8d. Traffic receipts show an increase of £6,988 compared with the corresponding half-year of 1909. Working expenses amounted to £75,652. 10s. 10d., an increase of £3,307. 1s. 7d. The directors have, before declaring the net profits, set apart £10,000 to renewal fund, leaving £123,297. 4s. 10d. Quarterly interim dividends of 15s. per cent. on the ordinary stock, and £1. 10s. per cent. on the preferred stock were paid on April 30, absorbing £52,500, and second quarterly interim dividends of 15s. per cent. on the ordinary stock, £1. 10s. per cent. on the preferred stock, amounting to £52,500, will be paid on 30th inst. The balance of £18,297. 4s. 10d. will be carried forward.

BOMBAY ELECTRIC SUPPLY & TRAMWAYS CO. (LTD.)—At the ordinary general meeting on Thursday last Sir E. Sassoon, who presided, said the net receipts were £82,695. 13s. 8d., compared with £67,066. 16s. 3d. the previous year. Deducting debenture interest (£30,530. 5s. 9d.) there remained £52,165. 7s. 11d., making with £9,385. 9s. 1d., brought forward, an available £61,550. 17s. Preference dividend absorbed £35,983. 13s., whilst provision for sinking fund had required a further £6,000, leaving £19,567. 4s. The directors recommended that £15,000 be placed to depreciation account, and £4,567. 4s. carried forward. Of the sum for depreciation they proposed that £10,000 be invested outside the business. Revenue was £197,827. 19s. 3d., increase £19,972. 7s. 6d., and this increase was obtained by an increased expenditure of only £4,343. 10s. 1d. Revenue from the tramways accounted for £8,628 of the gross increase, and the receipts from electricity supply accounted for £9,837. It had been decided to construct 10 new single-truck cars, each seating 38 passengers, which would be attached to existing cars, and run as double-car trains. The balance carried to profit and loss account in the electricity supply section was £16,618. 1s. 4d., compared with £7,976. 19s. 1d. The directors had decided to substitute flat rates for the maximum demand system. This would apply specially to the domestic consumption—to the supply for lighting and electric fans, as distinct from contracts entered into with large consumers of electrical energy for power for industrial purposes. Experience had shown that while scientifically sound in principle, the maximum demand system of charging was not equally satisfactory in practice where the conditions to be dealt with were those of an Oriental city. The new tariff had not yet received the concurrence of the municipality, but the municipality and the large majority of consumers were strongly in favour of flat rates.

BRITISH ELECTROMOBILE CO. (LTD.)—The directors' report for the year ended June 30 states that the profits were £363 and that the adverse balance brought forward is reduced to £241.

CENTRAL LONDON RAILWAY CO.—The directors' report for the half-year to June 30 states the traffic receipts were £146,586 (increase £2,927) and total gross receipts £158,339 (increase £4,597). Working expenses were £87,628 (decrease £1,974), leaving balance to net revenue account £70,711 (increase £6,571). After providing for debenture interest, &c., there remains £85,078. 16s. The directors recommend dividends at the rate of 3 per cent. on the undivided ordinary and 4 per cent. per annum on the preferred ordinary stock, and the balance of £45,805. 4s. carried forward. Passengers carried were 20,664,896 during the half-year (compared with 18,989,109 for the corresponding half of 1909.) A contract has been entered into for the construction of the extension of the Central London line from the Bank station to the Liverpool-street station of the Great Eastern Co., with a connection to the Broad-street station of the London & North-Western and North London Cos., and work has practically commenced. A contract has also been let for the making of the public subway between the Bank station of the Central London Railway and the booking hall of the City & South London Railway in King William-street, the cost of which will be borne equally by the two companies.

EAST LONDON RAILWAY CO—At the meeting of this company on Tuesday Lord Claud Hamilton dealt with the question of electrification, and quoted statistics showing the excellent results obtained by the electrification of the Mersey railway. He said that in the case of the East London they would not have to go in for large capital expenditure to provide a power station. Like the shareholders, he was getting very tired of beating about the bush, and he proposed, and his colleagues had already given their approval, to approach one or two of the great electrical companies and see whether they could submit a scheme—probably on the principle of deferred payments extending over several years—under which they would undertake to carry out the entire work of electrification. If he succeeded in coming to terms, he would be in a position to go with something concrete to the six lessee companies, and, he trusted, with some prospect of success.

LANARKSHIRE TRAMWAYS CO.—For the half-year ended June 30 the revenue was £36,181. 13s. 3d., and the expenses were £20,599. 8s. 6d. Deducting the contributions payable to local authorities (£825. 10s. 9d.) and interest (£608), and adding amount brought forward the balance is £15,477. 7s. 3d. The directors recommend a dividend at the rate of 5½ per cent. (£9,432. 10s.), leaving £6,044. 17s. 3d. to be carried to revenue new account. The traffic receipts show an increase of £4,058 over the corresponding period of last year, due to improved trade conditions and to extensions opened for public traffic July, 1909. The expenses show an increase of £2,913.

LIVERPOOL OVERHEAD RAILWAY CO.—The accounts for the past half-year show an available balance of £9,592. 15s. 6d., and the directors recommend payment of the preference dividend, leaving £5,916. 18s. 6d. to carry forward.

LONDON, BRIGHTON & SOUTH COAST RAILWAY CO.—The directors' report for the half-year to June 30 states that the electrical trains on the South London railway continue to work very successfully, and the increase of traffic since the services were established is still maintained. The board have decided to extend the electrical system to other parts of the suburban area served by the railways of the company, and the work of equipping the line from Peckham Rye, where a junction is made with the South London Railway, through Tulse-hill to the Crystal Palace, has already been commenced. The capital expenditure during the half-year included £28,148 for the electrical equipment of the South London line.

METROPOLITAN DISTRICT RAILWAY CO.—The directors recommend a dividend for the past half-year at the rate of 3 per cent. on the 5 per cent. extension preference stock, placing £10,000 to renewals and carrying forward £8,527. A year ago a distribution at the rate of 3 per cent. per annum was made on the 4 per cent. guaranteed stock and £10,000 placed to renewals.

METROPOLITAN RAILWAY CO.—At the meeting on Wednesday the chairman (Sir Chas. McLaren) said it was proposed to place £10,000 to the electrical renewal and depreciation fund, against £5,000 in the corresponding half-year, but the extra £5,000 was the sum received from the Great Western Railway Co. under a recent settlement for work done during the past three years. The board had entered into a contract with the British Westinghouse Co. for a renewal of a large portion of the generating machinery at Neasden, which would not only largely increase the capacity of the power station, but it was expected would result in considerable economy in coal consumption. They might congratulate themselves upon the result of the half-year's working, and look forward confidently to increases in dividend in the future.

MEXICAN LIGHT & POWER CO. (LTD.)—The directors' report for 1909 states that the development of the business and the work of construction have made satisfactory progress. The demand for power in

Digitized by Google

the City of Mexico and the Federal District increased so rapidly that it became necessary to press forward the completion of the entire hydro-electric works at Necaxa, and these are now rapidly approaching completion. By the construction of a series of tunnels and dams five large reservoirs have been formed, which will store a very large volume of water, thereby assuring a continuous supply of water during the entire year. On the completion of the work the hydro-electric power station at Necaxa will have a capacity of about 100,000 H.P., of which 50,000 H.P. is already used under peak loads. The carrying capacity of the high-voltage transmission lines also has been increased to 100,000 H.P. The accident in May, 1909, to one of the dams at Necaxa did not greatly add to the cost of construction and the completion of the dam was delayed only six months. The storage capacity of the five reservoirs is 129,500,000 cubic metres, but when the present works are completed it will be 173,000,000 cubic metres. It is anticipated that in future the company will not require to have recourse to steam power. The gross earnings for the year were $3,014,325, which, with $60,823 brought forward, made $3,075,149. From this has been deducted general operating expenses ($648,337), making the net revenue $2,426,811, out of which the management and fixed charges and the 7 per cent. preference dividend have been paid, leaving $1,186,528. From this surplus one-half of the extraordinary expenditure in connection with the operation of the steam plant has been deducted and a 4 per cent. dividend on the common stock has been paid, leaving $149,386 to be carried forward. Construction has been commenced on a branch transmission line from Necaxa to Pachuca and on a sub-station, and it is expected that power will be delivered from Necaxa by Sept. 1 next, when the Pachuca plant will be shut down, thereby reducing the operating cost.

MEXICO TRAMWAYS CO.—The net revenue (in gold for 1909, after paying expenses and fixed charges, amounted to $922,458, which, added to $371,350 brought forward, made $1,293,808. Four quarterly dividends at the rate of 6 per cent. per annum were paid, absorbing $577,464, leaving $716,344, out of which $300,000 has been carried to reserve as a special appropriation for depreciation, and $416,344 forward.

NEW GENERAL TRACTION CO. (LTD.)—The revenue for the year ended March 31 (received and accrued) amounted to £19,482. 1s. 10d., against £18,701. 8s. 9d. in the previous year. The general expenses were £1,792. 9s. 1d., against £1,990. 16s. 8d. The accounts show a profit of £500. 19s. 4d., after providing for the realised loss of £576. 11s. 11d. on the sale of $64,000 4½ per cent. first mortgage bonds of the Darby, Media & Chester Street Railway Co. and £1,500 towards depreciation of investments, thus reducing the balance of loss previously shown to £25,306.3s.9d. The dividend received from the Coventry Electric Tramways Co. for 1909 was the same as for the previous year (3½ per cent.); a dividend of 1¾ per cent. was received from the Norwich Co. (against 1¼ per cent.); the Douglas Southern Electric Tramways Co. paid 5 per cent. on its preference shares (compared with 5½ per cent.); and the income from the Philadelphia undertaking for the year was £10,324. 10s. 7d.

TRAFFORD POWER & LIGHT SUPPLY (LTD.)—The accounts for the year ended March 31 show a loss (after providing for interest) of £417 increasing the debit forward to £2,934.

VICTORIA FALLS & TRANSVAAL POWER CO.—At the recent meeting the Marquess of Winchester said they had few customers, but those customers had a large and increasing demand for power. Increased capital commitments had to be met by increasing the debenture issue To do that they must be able to prove that there was a substantial margin of revenue over and above that required to meet the debenture interest during the present year. They proposed to carry forward the balance profit on the past year's working. Not only had further contracts to take power been concluded, but certain of the contracting companies had also become financially interested as shareholders in the success of their undertaking. The Driehoek station, from the fact that the plant was not of an economical type, would have been closed down last year and merely retained as a stand-by until the installation of the more modern stations was completed, but owing to the increasing demands of the mining industry for power it was decided to keep the plant in commission. That, although not satisfactory from a revenue point of view, enabled them to give supplies to new consumers and to consolidate their position. Application had been made to the Transvaal Government to enable them to erect a new station on a suitable site selected.

NEW COMPANIES, &c.

NEW COMPANIES.

DAC ACCUMULATOR SYND. (LTD.)—(110,763).—Reg. July 13, capital £25,000 in £1 shares, to carry on the business of electrical engineers and contractors, manufacturers of and dealers in cells and batteries, suppliers of electricity, manufacturers of electrical and other apparatus, &c., and to adopt an agreement with G. Schauli, F. T. W. Price and H. E. Hughes for the acquisition of certain patents. First directors, F. T. W. Price and H. E. Hughes. Reg. office, 39, Red Cross-street, London, E.C.

DARTMOOR ELECTRIC SUPPLY CO. (LTD.) (110,871).—Reg. July 19, capital £4,000 in £1 shares, to carry on at Bovey Tracey and elsewhere the business of an electric light company and to adopt agreements with J. H. Lee and A. J. Wyatt. First directors, W. Aggett, H. A. Bentinck, J.P., D.L., H. Goodwyn, F.R.C.S., Lucy Hellier, W. G. Hole and P. W. Peters. Reg. office, 12, Market-street, Newton Abbott, Devon.

HOLOPHANE (LTD.) (110,941.)—Reg. July 22, capital £200,000 in £1 shares, to acquire from O. A. Mygatt, Paris, his interests in the Holophane system of illumination in all parts of the world, except France and the French Colonies, and including the business of O. A. Mygatt, 12, Carteret-street, S.W., and elsewhere as the Holophane Co., and all patents, secret processes, trade marks and designs relating to glassware for artificial lighting purposes belonging to the vendor. First directors, O. A. Mygatt, Lieut.-Col. F. J. P. Butler, G. C. Glynn, D.S.O., Lord E. W. Hamilton and R. Woodhouse, Jun. Reg. office, 12, Carteret-street, London, S.W.

METALITE (LTD. (110,919.)—Reg. July 21, capital £500,000 in £1 shares, to carry on the business of manufacturers of electric lamps, filaments, radiators, stoves, meters and fittings and apparatus and appliances of all kinds for use with electricity, and to acquire the businesses of the Bryant Trading Synd. (Ltd.) and International Filaments (Ltd.).

RECEIVERSHIPS.

BUCKHOLTZ REVERSIBLE TURBINE SYND. (LTD.)—Notice is made of the appointment of J. Ward, 4, Bennett-street, London, S.W., as receiver, on May 10, 1907, under powers contained in instrument dated Oct. 29, 1906. (Notified July 7.)

C. & A. MUSKER (1901) (LTD.)—Notice of the appointment of W. H. Walker, of 42, Castle-street, Liverpool, as receiver on June 29, under powers contained in trust deed dated July 8, 1901, has been filed.

NORFOLK ELECTRICAL CO. (LTD.)—Notice of the appointment of G. R. Ridsdale, of Winchester House, Birmingham, as receiver, on July 15, 1910, under powers contained in mortgage debentures dated July 22, 1908, has been filed.

WITNEY ELECTRIC SUPPLY CO. (LTD.)—Notice of the appointment of F. Habgood, of Witney, as receiver and manager, by order of Court dated July 15, 1910, has been filed.

CITY NOTES.

MEMORANDA (July 28).—**Bank rate 3 per cent. (since June 9, 1910). Price of silver,** 24⅛d. per oz. Consols 81⅞—81⅞ for money and for account. **Consols Pay Day, Aug. 4; Stock and Shares Continuation Days, Aug. 10 and 29; Ticket Days, Aug. 11 and 30; Pay Days,** Aug. 12 and 31; **Mining Shares Carry Over Day,** Aug. 9.

PRICES OF METALS (London).—*Copper*, cash, 54⅞; three months, 55¼. *Lead*, English, 12¾—13; foreign, 12⅝—12⅝. *Spelter*, 22¾—22¾. *Tin*, English, 148—149; foreign cash, 149½; three months, 150¼. *Iron*, Cleveland, cash, 48/8, three months, 49/5½.

BRISTOL TRAMWAYS & CARRIAGE CO. (LTD.)—The directors have declared an interim dividend at the rate of 4 per cent. for the half-year ended June 30.

BRITISH COLUMBIA ELECTRIC RAILWAY CO. (LTD.)—The directors have declared a dividend at the rate of 5 per cent. on the preferred ordinary stock for the half-year ended June 30, together with an additional dividend at the rate of 1 per cent. for the same period.

CHELSEA ELECTRICITY SUPPLY CO. (LTD.)—An interim dividend at the rate of 4 per cent. (2s. per share), less tax, has been declared on the ordinary shares for the past half-year.

CITY OF BUENOS AYRES TRAMWAYS CO. (1904) (LTD.)—The director have declared a dividend of 1s. 3d. per share (less tax) for the three months ended June 30.

DUBLIN & LUCAN ELECTRIC RAILWAY CO.—After payment of debenture interest the directors propose a dividend at the rate of 5 per cent. on the preference shares for the six months ended June and to carry forward £612.

ICELAND.—At the meeting of the Industrial & Engineering Trust on Friday the Chairman, Mr. F. L. Rawson, said the British North-Western Synd. (Ltd.) had an option to purchase for about £12,000 practically the whole interest in Dettifoss Falls which were capable of developing about 720,000 H.P.—nearly three times as much as the largest falls in Europe. He had had these falls valued by Mr. Hjorth (probably the leading authority in the world on water power), who had valued them at £900,000. There should be no difficulty in forming companies for the utilisation of the power, as it could be delivered on the quay side at a cost of about 11s. per H.P. per annum. This was the most economical power that he knew of anywhere in the world.

KENSINGTON & KNIGHTSBRIDGE ELECTRIC LIGHTING CO. (LTD.)—The directors have declared an interim dividend on the ordinary shares for the half-year ended June 30 at the rate of 8 per cent., payable 15th prox.

LISBON ELECTRIC TRAMWAYS CO. (LTD.)—An interim dividend of 3 per cent. (tax free) has been declared on account of the earnings for the current year.

METROPOLITAN ELECTRIC SUPPLY CO. (LTD.)—The directors have declared an interim dividend at the rate of 4 per cent. for the half-year to June 30.

MONTREAL LIGHT, HEAT & POWER CO. (LTD.)—The directors have declared a dividend of 1¾ per cent. on the paid-up capital stock (at the rate of 7 per cent. per annum) for the quarter to 31st inst.

NOTES.

Street Lighting in the City of London.

THE report of Mr. F. SUMNER, engineer to the City of London, is always interesting, owing to the particulars given of the competitive forms of street lighting. Turning first to electric lighting, we notice that the companies are beginning to see that it is worth while to replace some of the old types of arc lamps, which still adorn the streets in certain quarters, by something more modern. Thus the City of London Co., on their own initiative, have substituted Oliver flame arc lamps for open type lamps in certain streets, the Corporation gaining by this move an advantage of a decreased cost of £8. 10s. per lamp per annum. We think that this policy is wholly desirable; in fact, it may be said to be imperative if street lighting with electric arc lamps is to obtain that popular support which is necessary at the present time. In regard to defective electric lamps, it is stated that 52 cases of this kind were reported during the year, the number of lamps in use being 447. Turning to that part of the report referring to gas lighting, the number of defects appears to be more serious. In ordinary incandescent gas lamps, there were 1,276 cases of feeble light and 20 cases of total failure. In addition there were 199 defects in lanterns, burners, &c., and the total number of defects was 1,841, viz., 1,495 in ordinary gas lamps and 346 in high-pressure lamps. As the total number of gas lamps is 2,720, it will be seen that the electric lamps show to considerable advantage. Another point to which attention is drawn is the synchronising of clocks. It will be remembered that in 1903 a by-law was passed by the City Corporation to the effect that any public clocks erected after that date were to be synchronised. This regulation, however, has not produced a very marked effect because most of the clocks were erected before the rule was made. It is really unfortunate that when the Corporation went so far as to make a regulation they did not make it retrospective and thus obtain a truly accurate time service throughout the City.

Metal Filament Economies.

THE position of the Leeds electricity undertaking during the last year or two has been so unusual that it is certainly worthy of mention. In spite of the fact that new consumers continue to be connected to the mains at a very satisfactory rate, the output of energy remains almost stationary, the total number of units sold during the past year being practically the same as two years ago. When it is seen that the sales of energy for power and heating have during this period increased by considerably over 1,000,000 units, it will be evident how great is the reduction that has taken place in the revenue obtained from lighting. As a matter of fact, the receipts from private lighting were for the past year only £64,518, as against £80,928 two years ago, notwithstanding a large influx of new consumers. This result is largely accounted for by the increasing use of metal filament lamps, with their resultant economy in current consumption. Moreover, the consumption per lamp installed is also decreasing. Thus, whereas in 1907-8 the number of units sold for private lighting per 35-watt lamp installed was 21¼, in the past year this figure fell to 17¾ units. This value appears to have been carefully obtained, and is not based merely on the hypothetical 8 c.p. lamp. As in practically all cases an increased amount of light is being obtained, electricity consumers in Leeds have evidently fully appreciated the great possibilities in the way of economy conferred by the new types of lamp. That electric lighting is also no longer a luxury can be gathered from the fact that the average price per unit sold for lighting was last year only 3·02d., the average figure for the whole supply of 12½ million units being 1·91d. The present position of course, will be quite altered when the change-over by consumers to metal lamps is completed; and as the supply of energy for power has shown considerable progress in spite of trade depression, we shall look at an early date

Digitized by Google

for a rapid expansion of the undertaking. Even as it is, a sum of £8,930 has been handed over to the relief of the rates, but we regret that further provision is not being made for renewals.

WHEN it is remembered that the Leeds undertaking has not the benefit of a traction load, the excellence of the low figure at which the costs now stand is emphasised. Thus, with a load factor of only 15·9 per cent., the total costs per unit sold, excluding capital charges, are only 0·59d., fuel costing the remarkably low amount of 0·17d. per unit, a record figure, we believe, in the history of electricity supply, and one certainly reflecting great credit on Mr. H. DICKINSON, the city electrical engineer. The great reduction in the works' costs on the present occasion, compared with last year's and previous results, is probably largely accounted for by the turbo-generators which were recently installed, and which are apparently making considerable impression on the cost of generation. The striking economies introduced without any expansion of the output are certainly most instructive, as showing the difference between central station practice a few years ago and at the present time.

Competition by our Gas Friends.

So keen has the competition of our gas friends become that it is almost another term for "up-to-dateness" in that particular line. The following method, however, which is described in a letter we have received from a well-known London station engineer, is not merely up-to-date, but distinctly before its time:—

> Electrical engineers whose Councils are considering the lighting of their streets by metallic filament lamps, or who at present use this means of lighting, are warned that recently a gas company in London was found to remove temporarily the lamps from columns during lighting hours, their object in doing so being stated to be "for testing." Viewing the fragile character of the metallic filament lamp, it cannot be stated to be just competition to tamper with such apparatus; moreover, the fact that all tests as to efficiency of lighting can be carried out without interfering with the source of light, whether it is gas or electric, renders such an action unjustifiable. Although one cannot but admire the persistence with which the gas companies are waging a hopeless warfare in endeavouring to re-capture street lighting, I think they have overstepped the bounds of commercial morality, and have at the same time committed a breach of the law.

Such a proceeding appears to be most unjustifiable. Obviously a gas company has no right to tamper with electric lamps used in street lighting, though occasions may arise when some control is desired. Supposing, for example, that it was desired to extinguish some electric lamps for the purpose of making photometric tests of adjacent gas lamps, it would be merely common courtesy to request the electricity supply undertaking to switch off the lamps in question rather than to usurp any such authority. There is not likely to be any difficulty in following such a course. In the present instance there does not seem, so far as we can judge, to have been any photometric testing, but merely a wholly unnecessary examination of the lamps. From the point of view of the electricity undertaking such examination of lamps in competition is very undesirable, and unworthy motives suggest themselves. Considering the delicate position in which competitors find themselves under these conditions, we hope that the gas company concerned will see the obvious desirability of restraining the efforts of their staff.

Shop Window Fires.

THE accounts in the daily Press of the serious fire which occurred in a draper's shop at Accrington on Saturday last, involving the loss of five lives, have again drawn the attention of the public to the possible risks where electric lamps are employed in shop windows in close proximity to inflammable goods. Unfortunately, if the fire be held to have been of electrical origin—a fact not always easy to ascertain, with the result that electricity is frequently blamed in the absence of conclusive evidence as to the real cause of the outbreak—emphasis will be laid on the dangers of electric light generally, instead of on the indiscriminate use of flexible wires and lamps among the very inflammable goods, such as cotton wool, exhibited in shop windows. At the inquest on Wednesday we notice that Mr. H. GRAY, electrical engineer to the Accrington Corporation, commented on this dangerous practice, and mentioned that in some cases he believed goods were even pinned to the wires. In most cases the risks, although small, are not appreciated; but a periodical inspection of all installations by members of the staff of electricity supply authorities, when the attention of consumers could be called to the necessity of greater care in shop window illumination, would be of great service, since the number of fires during the past year must have caused shop owners serious anxiety. In the present instance the origin of the fire has not yet been definitely stated, but it is noticeable that the "bursting of an electric lamp" is becoming as stereotyped an expression of the non-technical reporter as the "fusing of an electric wire" has been in the past.

Personal.—Mr. A. C. Forshaw, the London superintendent of the Direct United States Cable Co., retired on pension at the end of July, after 36 years' service. The best wishes of all his old colleagues follow him in his retirement.

It is announced that Mr. George Westinghouse has been succeeded as president of the Westinghouse Electric & Mfg. Co. of America by Mr. Edward Atkins.

Automatic Telephony.—Consul E. Vicars, in his report on the Lyons district for 1909, states that the extensive trial of the Lorimer auto-commutator apparatus for automatic or exchangeless telephony was concluded in the autumn, after a year's duration, and may be pronounced a success; but it appears doubtful whether the Government will take up the invention, partly on account of its complicated, delicate and costly nature and partly by reason of the wholesale dismissal of women operators which its general adoption would entail.

Electric Traction in Copenhagen.—We understand that the Corporation of Copenhagen have decided to take over the working of the electric tramways in that city from August, 1911. According to the terms of the concession the tramways would revert to the city after 30 years from 1898, but could be taken over at a fixed price at the beginning of three-year periods, commencing with 1908. The decision of the Corporation to take over the tramways is against public opinion. The tramways in question include 25·5 miles of double track and 10 miles of single track, over which system operate 279 motor-cars and 191 trailers (five of which are single horse cars). Last year the tramways carried 70,949,345 passengers, and about 8,000,000 motor-car miles were run. It is feared that the result of the purchase will be an increase in the fares. At present a uniform fare of 1½d. is charged for all distances.

The late Harry W. Cox.—Amongst other contributions received by Sir William Treloar to the fund on behalf of the widow of the late Mr. H. W. Cox, is a cheque of £150 from His Majesty's Royal Bounty, upon the recommendation of the Prime Minister.

Traction Problems in Pittsburg.—The question of how best to obtain really rapid transit between the centre of the town and the suburbs has long been exercising the minds of the municipal authorities of Pittsburg, with the result that they called on Mr. Bion J. Arnold to look into the matter. Mr. Arnold, whose report has just been issued, deals in detail with the solutions available, namely, an elevated railway, a subway, or the electrification of the existing steam suburban lines. The first of these is at once ruled out of court and the second accepted as being the best solution. It is estimated that a subway would cost between £200,000 and £400,000 per mile of single track, and that this expenditure should not be undertaken unless at least £6,000,000 is to be spent. The average annual earnings are estimated at 12 per cent. of the capital expenditure. These earnings will not increase appreciably with any increase in population, as extensions will then become necessary. The problems of routing and re-routing are gone into, but as these depend on the system of uniform fares, the conclusions arrived at are not applicable in this country.

Change of Resistance of Metals in a Magnetic Field at Different Temperatures.—In a recent issue of the "Philosophical Magazine," Mr. S. C. Laws describes a series of experiments carried out in the Physics Laboratory of the Blackburn Municipal Technical School on this subject. The results reached may be summarised as follows:—(1) In the case of the substances examined—cadmium, zinc and graphite—the change of resistance, $\delta r/r$, in a magnetic field H, is proportional to H^2 for the range of fields used. (2) This change of resistance in all cases increases at lower temperatures; for the metals cadmium and zinc $\frac{1}{H^2}\frac{\delta r}{r}$ at the temperature of liquid air is about 20 times as large as at atmospheric temperatures, while for graphite $\frac{1}{H^2}\frac{\delta r}{r}$ shows only a threefold change over this range of temperature. (3) The increase of resistance, $\delta r/r$, in the case of graphite is about 1 per cent. in a field of 11,000 C.G.S. units at atmospheric temperatures; this is about equal to the *decrease* of resistance of nickel in the same field, and is many times larger than the change of resistance occurring in any of the non-magnetic metals hitherto examined except bismuth.

Electrical Towing at Bremen.—According to "The Times Engineering Supplement," when the city of Bremen some time ago decided to resort to electrical towing for dealing with part of the navigation at the mouth of the Weser, ordinary towing locomotives were found inadmissible on account of the special local conditions. Two tracks of rails would have been required on the crest of the wall separating the two Weser sluices, which would have entailed the necessity of strengthening the wall at considerable outlay. Moreover, the top of the wall was occupied with the control apparatus of the sluice doors, and the traffic would have been impeded by the presence of so many rails. The following plan suggested by the Allgemeine Elektricitäts-Gesellschaft was therefore adopted:—A single line of rails was laid close to each of the outer edges of the wall where its strength was a maximum, thus leaving the remainder of the wall crest free. The usual form of locomotive was abandoned, and, instead, the engine was designed in the shape of a gantry of sufficient height to pass over the controlling devices, operators' cabins, conductor poles, &c. The necessity of passing under a passenger bridge, which is eventually to be erected, had also to be taken into account. The motor which is arranged on the top at the level of the cross-arm is of the three-phase type and drives the locomotive by means of intermediate gearing. The two wheels on each side of the engine are coupled together so as fully to utilise the adhesive force. The required pull of 1½ tons was readily obtained at the tests on delivery. The engine is manipulated by reversing controllers located on both sides immediately beside the controllers for the winches that operate the towing cable. These two winches which are placed in the upper cross-arm enable the towing cable to be let out to a length of upwards of 100 metres. In connection with this towing plant electric lighting plant for the sluice wall was installed. This comprises 18 poles, which are each provided with two 50 c.p. A.E.G. filament lamps, and at the same time carry the supports for the overhead wires feeding the locomotives. The 7,000 volt three-phase current derived from the municipal electricity works is reduced to 220 volts in a special transformer house before being supplied by water-tight cables through the sluice to the lamps and the overhead wires of the locomotive.

Current Topics.

Subjects of current interest dealt with in this issue include the following:—

We complete our description of the plant laid down by the Anglo-Newfoundland Development Co. for the manufacture of paper from wood pulp, the paper being used for the printing of the "Daily Mail" and other papers of the Amalgamated Newspaper Co.

We give an account of Dr. Schönherr's system of producing nitrates from the atmosphere.

Last week a joint meeting of the Institution of Mechanical Engineers and the American Society of Mechanical Engineers was held, and five Papers dealing with the electrification of railways were read. We give an abstract of three of these in the present issue, and an account of the discussion which followed.

The Annual Report of the Engineer of the City of London contains interesting details in regard to the public lighting.

The installation of wireless apparatus on board ships carrying 50 or more persons, and plying between ports over 200 miles apart, is compulsory according to a law recently passed in the U.S.A. The Act is fully set out elsewhere. A similar measure is before the British Parliament.

An effort is being made by the Postmaster-General to substitute the telephone for boy messengers in delivering telegrams.

It would appear from a report by Consul-General Smith that the disadvantages outweigh the advantages of exhibiting machinery at Russian exhibitions.

It is curious that the death of one railway servant has occurred in each of the years 1904-5-6-7-8-9 on the electric lines of railway in this country. As regards non-fatal accidents, the record of these lines is satisfactory.

Wireless telegraphy on railways is reported to have proved a success in Brazil.

A 12 months trial at Lyons (France) of the Lorimer "auto-commutator" apparatus for automatic or exchangeless telephony is said to have proved a success.

Tenders are invited by the Minister of Telegraphs for the supply and erection of five wireless telegraph installations in New Zealand.

Frome Urban Council have sealed the agreement with Edmundsons Electricity Corpn. for the transfer of their electricity undertaking to that company. The terms seem to be somewhat different from those usually arranged, and are interesting from that standpoint.

Legal.—An important judgment was delivered by Mr. Justice Neville on Friday last in the action brought by the Attorney General (ex rel. the India Rubber Gutta Percha & Telegraph Works Co.), against West Ham Corporation declaring that bankers' overdrafts for the electricity undertaking were ultra vires.

Companies' Meetings.—At the meeting of the South Eastern and Chatham Railway Companies there was an opinion expressed that the time was approaching when the joint companies would wisely take into urgent consideration the question of electrification.

At the meeting of the London, Brighton & South Coast Railway Co. on Wednesday the chairman referred to the continued success of the electrical train services on the South London Railway, and announced that the lines from Peckham Rye to the Crystal Palace and from Battersea Park to West Norwood were now in course of equipment for electrical working.

The meeting of the Anglo-American Telegraph Co. on Friday last week was made additionally interesting by the particulars given by the chairman concerning the negotiations which have been taking place between the Company and the American Telephone & Telegraph Co. in connection with the laying of another cable across the Atlantic, which, we understand, is to be the largest cored cable of any yet manufactured for this service.

INSTITUTIONS AND SOCIETIES.

Institution of Mechanical Engineers.—It is a recognised axiom of British civilisation that the best way to entertain a fellow creature whom one particularly wishes to impress with one's own benevolence is to give him a good dinner. It was therefore only fitting that the joint Meeting of the Institution of Mechanical Engineers and the American Society of Mechanical Engineers, which was in progress last week, both in Birmingham and London, should be brought to a conclusion on Friday evening last by an entertainment of the prandial kind given by the British Institution to their American colleagues. The occasion was unique in another way; for it is our ungallant habit in this country to exclude ladies on these occasions, but at this particular dinner this rule was relaxed and invitations were extended to the fairer sex; and whether for this reason, or on account of the leaven provided by our American colleagues, it seemed to us that the proceedings went with much more go than is usual.

The dinner was held at the Connaught Rooms, Great Queen-street, under the chairmanship of Mr. J. A. F. Aspinall, President of the British Institution. The company was seated at 63 small tables, among those present being the United States Ambassador (Mr. Whitelaw Reid), Mrs. Aspinall, Dr. W. F. M. Goss (vice-president of the American Society of Mechanical Engineers), Mrs. Goss, Mr. James M. Dodge (past president A.S.M.E.), Mr. Oberlin Smith (past president) and Mrs. Oberlin Smith, Mr. A. H. D. R. Steel-Maitland, M.P., Sir W. and Lady White, Dr. Worcester, Mr. and Mrs. Hartley Wicksteed, Dr. and Mrs. F. W. Taylor, Dr. and Mrs. Wm. Maw, Mr. C. Hawksley, the Mayor and Mayoress of Windsor, Prof. and Mrs. Hutton, Dr. and Mrs. A. Swasey, Mr. E. P. Martin, Dr. W. C. and Miss Unwin, Mr. C. Kirchhoff, Mr. J. L. Griffiths (U.S. Vice Consul), Dr. and Mrs. J. Freeman, Sir Gerard Muntz (president, Institute of Metals), and Lady Muntz, Dr. and Mrs. R. T. Glazebrook, Mr. Henry Lea, Mr. C. F. Scott, Mr. and Mrs. J. Smith, Mr. and Mrs. J. Hartness, Mr. W. F. Marwood (Board of Trade), the Hon. William and Mrs. Wiley, Mr. Calvin Rice, Mr. and Mrs. Willis Hall, Mr. and Mrs. E. B. Ellington, Mr. and Mrs. Henry Gantt, Dr. and Mrs. Tudsbery, Mr. H. J. Grant, Mr. and Mrs. Mark Robinson, Mr. Frank Ree (L. & N.W.R.), and Mrs. Ree, Mr. and Mrs. A. Herbert, Mr. H. F. Donaldson, Mr. and Mrs. H. Heaton, Mr. F. M. Lea, Mrs. Angus Sinclair, and Dr. Hele Shaw.

The loyal toasts having been honoured with enthusiasm, Mr. ASPINALL, in the absence of the Lord Chief Justice, proposed "The Health of the President of the United States." He said that it sometimes occurred to him that the United States was like a great kaleidoscope, perfect in design and absolutely scientific in arrangement, but changing with the slightest movement, though always remaining uniformly symmetrical, each section pointing to a common centre towards which all the races forming the nation were tending—the Stars and Stripes.

The AMERICAN AMBASSADOR, on rising to reply, was received with prolonged cheers, not only from the American but from the British guests. He said that all Americans would appreciate the kindly terms in which the toast had been proposed, and he felt sure he was authorised to thank Mr. Aspinall and every Englishman present for the sentiments that had been expressed. He drew attention to the way in which the civilisation of the twentieth century had been influenced by the work of the mechanical engineer. Could the twentieth century be conceived, he asked, without the development made by the contributions of Watt and Fulton? Could the English speaking world of to-day be conceived without the lesser, but still gigantic, contributions of other mechanical engineers of the same common race—Stephenson, Fairbairn, Whitney Morse, McCormick, and at the present time Edison, Bell and Westinghouse? Those, like themselves, who had achieved such results and developed such a civilisation, were bound above others to seek constantly for its preservation. Influences were abroad tending to impair or destroy it, so that there was no safety for the work which they had built up and must preserve, save in obedience to law, in protection to life, and in those twin and vital safeguards, equal protection to individual liberty and to individual property, which was shadowed in that respect for authority that their toast enforced. In conclusion, he mentioned that it would, perhaps, be wise for the toast of the President of the United States to be honoured in the same way as that of the King—that is without reply. One thing was clear. The toast of these two great heads of States of the English speaking world were being more and more honoured in the same spirit on both sides of the Atlantic with the same loyal and patriotic hope for the continued sovereignty of law, and the preservation of ordered liberty, which was the real meaning of each of them.

Sir WILLIAM WHITE, in proposing the toast of "The American Society of Mechanical Engineers," mentioned the fact that it was founded only 30 years ago and now had a membership of about 4,000. Both societies had common objects and common ideals, and with a common desire to do their duty in the cause of humanity were being drawn closer and closer together. In the maintenance of law and order and the repression of rebellion and wrong the mechanical engineer bore an important part, and the cause of liberty and truth owed much to him.

This toast was replied to by Prof. HUTTON, Hon. Secretary of the American Society of Mechanical Engineers, in a thoroughly characteristic speech. After paying a tribute to the memory of King Edward, he went on to read into the joint meeting a broader significance than would be given by simply a gathering of friends. The American was so much at home in the United Kingdom because he and his host had a common ideal. As long as they had that common ideal, their civilisation rested on a bed-rock so massive that there was no force which could ever shake the nations apart. The reason why Englishmen had lost work which Americans had secured was that the latter had learned the trick of having the specifications written by the seller and his engineer, whereas the Englishman insisted upon having the specification written by the buyer or his engineer; but when the buyer purchased the standard product of the American engineer he bought what he wanted.

Other toasts were "Our Other Guests," given by Mr. E. B. Ellington, Vice-President of the Institution of Mechanical Engineers, and replied to by Dr. Glazebrook, while "Success to the Institution" was proposed by Dr. W. F. M. Goss and acknowledged by Mr. Aspinall.

Mr. J. A. F. Aspinall and the Council of the Institution of Mechanical Engineers gave a conversazione at the Institution, Storey's Gate, on Thursday last in connection with the joint Summer Meeting of the Institution of Mechanical Engineers and the American Society of Mechanical Engineers. The proceedings were rendered more attractive by a number of short lectures, among them being one by Dr. Hele Shaw on "Streamline Experiments Illustrating Aeroplane Stability," while a musical programme was performed by a number of artistes and by the String Band of the Royal Artillery.

British Association.—A provisional programme of the sectional and other meetings of this Association at its annual meeting, which will take place at Sheffield from August 31 to September 6, has now been issued. The reception room will be at the Cutler's Hall and will include a large luncheon room. All the various meeting places are grouped within a radius of 400 yds. from this hall. The president's address and the popular lectures will be given in the Victoria Hall.

In Section A (Mathematical and Physical Sciences), the address of the president (Prof. E. W. Hobson, F.R.S.) will be delivered at 10 a.m. on Thursday, September 1. Two discussions are being arranged. On Monday, September 5, there will be a joint discussion with Section G on the Principles of Mechanical Flight, to be opened by Prof. G. H. Bryan, F.R.S.; and on Tuesday, September 6, Dr. C. Chree, F.R.S., will open one on Atmospheric Electricity. The section will meet with Sections G and B on Friday, September 2, to participate in the discussion on the report of the Gaseous Explosions Committee, and in the Papers which follow dealing with combustion. Several Papers have been promised to the Section, but the programme is still incomplete.

In Section B (Chemistry) the feature is the joint discussions with other sections. Among these may be mentioned "The Neglect of Science by Commerce," with Section L, and on "Combustion" with Sections A and G.

In Section G (Engineering) the presidential address will be delivered by Prof. W. E. Dalby, while Papers will be read on "The Testing of Lathe Tool Steels," and "A New Method of Testing the Cutting Quality of Files," by Prof Ripper; "Experiments on Aeroplanes," by Mr. W. A. Scoble; "Accelerometers," by Mr. H. S. Wimperis; "Optical Determination of Stress," by Prof. Coker; "Laws of Electro-Mechanics," by Prof. S. P. Thompson, F.R.S.; "The Electrification of the Brighton Railway," by Mr. P. Dawson; "Heat Insulation," by Mr. F. Bacon. The Gaseous Explosions Committee will make their report and there will be joint discussion on "Combustion" with Section B and on "Aerial Flight" with Section A.

Crystal Palace School of Engineering.—In the course of an address to the students of this school last Friday, Mr. J. C. Inglis, President of the Institution of Civil Engineers, remarked that it was not enough for students to confine themselves entirely to one branch of engineering; they should take a general view and try to master the principles in more than one direction. Transport would become an increasingly important subject, and there was sure to be an extended demand for the services of those who studied railway engineering.

PROBLEMS OF RAILWAY ELECTRIFICATION.

On Friday last, July 29th, a joint meeting of the Institution of Mechanical Engineers and of the American Society of Mechanical Engineers was held at the Institution of Civil Engineers, Westminster, the subject under discussion being the electrification of railways. The Papers read were as follows: "The Electrification of Railways," by Mr. G. Westinghouse (President, American Society of Mechanical Engineers); "Economies of Railway Electrification," by Mr. W. B. Potter; "The Electrification of Trunk Lines," by Mr. L. R. Pomeroy; "Electrification of Suburban Railways," by Mr. F. W. Carter; and "The Cost of Electrically-propelled Suburban Trains," by Mr. H. M. Hobart.

Abstracts of the Papers by Mr. G. Westinghouse, Mr. W. B. Potter and Mr. H. M. Hobart are given below. The first of these Papers was read, in the absence of the author, by Mr. C. F. Scott, who, in conclusion, remarked that Mr. Westinghouse said he would like to have some one at the meeting who appreciated the author's purpose and motive in preparing this Paper. Mr. Westinghouse wished to remind them that several years ago when the question of the compulsory electrification of railways in tunnels and terminals was before the New York Legislature, and about the time of certain tunnel disasters, both in America and in Europe, he advocated the use of steel cars. He was severely criticised in some quarters, but he adhered to his suggestion, and now steel passenger cars were becoming the standard for that type of service in America. At the present time Mr. Westinghouse was endeavouring to give his best attention, from the railway standpoint, to the matter of electrification and thus to do a future service to railways.

An account of the joint discussion on these papers will be found on p. 701.

THE ELECTRIFICATION OF RAILWAYS.*

BY GEORGE WESTINGHOUSE.

Summary.—In this Paper the author calls attention to the need which exists at the present time for a system of electric traction that can be universally used. Besides uniformity in gauge, vehicles and brakes, agreement is also required in the system of electrical energy used and the way in which it is supplied. The requisites for a universal electric system are noted, and the future of electrification of railways is gone into. Appendixes deal with the design of the electric locomotives now in use in America and the different systems of electrification employed, while data of the lines operated by electricity are also given.

It is my intention in this paper to direct attention to the necessity for the very early selection of a comprehensive electrical system embracing fundamental standards of construction which must be accepted by all railway companies in order to ensure a continuance of that interchange of traffic which, through force of circumstances, has become practically universal, to the great advantage of transportation companies and of the public. The time is ripe for such a selection unless we are willing to regard with complacency the extension of the existing diversified systems and the creation of conditions which will prevent the general use of the most practical methods of operation. Indeed, the tendency seems to be toward diversity rather than unity, since different types of third-rail construction have been adopted, even for the several continuous-current systems in and about New York City, which renders interchange of cars or locomotives difficult or impossible.

Although the facts clearly show the contrary, there exists a popular impression that the electrification of railways is a simple matter, and that it requires only decisions by boards of directors to ensure the immediate substitution of the electric for the steam locomotive. The great difficulty in the electrification of standard railways is no longer the engineering problem of developing a locomotive and an electrical system which will operate trains, but it is a broad question of financial and general policy of far-reaching scope, considering the future electrification of railways in general as distinguished from isolated cases of limited extent, and requiring a combination of the highest engineering and commercial skill.

To ensure interchange of traffic, the fundamental requirements, so far as operation by steam is concerned, with full regard for safety, speed and comfort, are very few in number and are covered by the following: A standard gauge of track, a standard or interchangeable type of coupling for vehicles, a uniform interchangeable type of brake apparatus, interchangeable heating apparatus and a uniform system of train signals. The additional fundamental requirements for electrically-operated railways are: A supply of electricity of uniform quality as to voltage and frequency, conductors to convey this electricity so uniformly located with reference to the rails that, without change of any kind, an electrically-fitted locomotive or car of any company can collect its supply of current when upon the lines of other companies, and uniform apparatus for the control of electric supply whereby two or more electrically-fitted locomotives or cars from different lines can be operated together from one locomotive or car. Outside of economy in capital expenditure, and economy and convenience in operation by steam or electricity, it matters not whether each locomotive and car and the apparatus upon them differ from every other locomotive and car in size or details of construction so long as the constructions are operative and the materials employed are used within safe limits.

The development of alternating-current apparatus from the earliest time is then gone into by the author.

The various systems of electrical working on railways now employed are then described, and it is shown that they are all fundamentally alternating-current systems, while the essentials of a good railway motor, both of the continuous and alternating-current type are also considered. Locomotives equipped with each of the three types of motors have been in successful operation and have demonstrated their usefulness, capacity and reliability in practical railway service. The three-phase motor, having a definite constant-speed characteristic, is particularly adapted to certain conditions; but, on the other hand, it has a less general adaptability to the ordinary varying conditions of railway operation. The single-phase motor has a facility of voltage control which gives an efficient means of speed adjustment, and is in this particular superior to other systems. The relative weights and costs of the several types of motors, and of the locomotives designed to accommodate them, depend upon so many conditions that comparisons must necessarily be general. It will be found, however, that these differences in locomotive cost are in many cases more than offset by the cost of the other elements in the electrical system.

The controlling factor in the cost of electrification in nearly all cases is the system for transmitting power from the power house to the locomotive, and not the locomotive itself. The choice between the several systems must, therefore, be based upon a comparison of the complete systems. The differences between the methods of transmitting power are of far greater importance than the differences between power houses or between locomotives. The current for all systems is generated in usual practice as high-tension alternating current, for the reason that electric energy can be most economically transmitted by high-tension alternating current even though it is in some cases converted into direct current.

In selecting a proper electrical system for railway operation, it will probably be generally conceded that the following elements are of prime importance: The electric locomotives should be capable of performing the same kinds of service which the steam locomotives now perform. This will be most readily secured by electric locomotives which can practically duplicate the steam locomotives in speed and power characteristics. This includes a wide range of performance, embracing through passenger service at different schedule speeds; local passenger service; through freight service in heavy trains; the handling

* Abstract

Digitized by Google

of local freight by short trains; and a variety of switching, terminal and transfer movements, and naturally calls for wide variation in tractive effort and in speed, both for the operation of different kinds of trains and also for the operation of the same train under the varying conditions usually incident to railway service. The electric locomotive should be capable of exceeding the steam locomotive in its power capacity. It should be able to handle heavier trains and loads, to operate at higher speeds, and in general to exceed the ordinary limits of the steam locomotive in these respects. The readiness with which several electric locomotives can be operated as a single unit enables any amount of power to be applied to a train. The electric system should adapt itself to requirements beyond the ordinary limitations of the steam locomotive in small as well as large things. It should be adapted for use on branch lines, and for light passenger and freight service similar to that so profitably conducted by interurban electric roads, which in many cases run parallel to steam roads, not only taking away the traffic of the steam roads, but building up a new and highly profitable traffic, both in passenger and in express service. A universal electrical system requires that power should be transmitted economically over long distances and supplied to the contact conductor. The system should utilise the most highly perfected apparatus for the electric transmission of energy and its transformation into suitable pressures for use. The contact conductor in an ideal system should be economical to construct, both for the heaviest locomotives where the traffic is dense, and for light service on branch lines. It should impose minimum inconvenience to track maintenance, should give minimum probability of disarrangement in case of derailment, or in case of snow and sleet, and should in general be so placed and constructed as to give a maximum assurance of continuity of service.

The use now made of electricity in steam railway service has been brought about, generally speaking, through compulsion. The steam locomotive has reached its limitations and has been found unsuitable and inadequate in tunnels or in terminal service. Even where other considerations may have been controlling, the problem has usually been a specific one of electrifying a relatively small area. The problem has been solved by considering those factors which were of immediate importance, without giving weight to uniformity with other systems or of extension.

Now the natural course of development will be the extension of these limited zones, until after a time they meet. Then there will arise great inconvenience and expense if the systems are unlike. For the present it may be a matter of little moment whether different systems have their contact conductors in the same position, or whether the character of the current used is the same or different. In the early days of railway work, it was of little consequence whether the tracks of the different systems in various parts of the country were alike or unlike, but later on it did make a vital difference, and the variation resulted in financial burdens which even yet lie heavily on some railways. It is this large view into the future of electrical service which should be taken by those responsible for electric railway development.

The complete electrification of a railway will necessitate a rearrangement of ideas and practices in regard to operations. Coaling and watering places will not be needed; passenger trains will be differently composed, some classes being of less weight, and they will operate more frequently, thus promoting travel; other trains will be heavier than at present, or will operate at higher speeds; and branch lines, by the use of electrically-fitted cars, can be given a through service not now enjoyed. The movement of freight will undergo great changes, due to the fact that electric locomotives can be constructed with great excess capacity, enabling them to move longer trains at schedule speed on rising gradients. The large percentage of shunting operations due entirely to the use of steam locomotives will no longer be required. The railway companies can combine upon some co-operative plan for the generation of electricity, thereby effecting large savings in capital expenditures, and can utilise their own rights of way for the transmission of the current, not only for the operation of trains but for many other useful purposes.

Notwithstanding the fact that great strides have already been made in cheapening the cost of generating electricity by steam engines, I foresee, from the progress made in the development of gas and oil engine power, a still further reduction in cost which will accelerate the work of electrifying existing railways.

One important aspect of this great question will engage the thoughtful consideration of every Government, namely, the military necessity for uniform railway equipment in time of war.

There will be serious difficulties to surmount in the selection of a general system. There naturally will be arguments in favour of one or another of the systems now in use and the inclination of those who have adopted a particular system to advocate its general use. There will be enthusiastic inventors, and there will be many advocates of the common view, namely, that there is room for several systems and that each system will best meet the requirements of a particular case. There will be those who give undue weight to some feature of minor importance, such as a particular type of motor or of locomotive, instead of giving a broad consideration to the whole system, and recognising that, in the general problem of railway electrification, facility and economy in transmitting power from the power house to the locomotive are of controlling importance.

Were there now only one system to be considered, there would be a concentration of the energy of thousands on the perfecting and simplifying of the apparatus for that system, to the advantage of railway companies and of manufacturers.

In conclusion, I can only repeat, and earnestly recommend to the serious consideration of railway engineers and those in authority, the pressing need of determining the system which admits of the largest extension of railway electrification and of a prompt selection of those standards of electrification which will render possible a complete interchange of traffic in order to save expense in the future and to avoid difficulties and delays certain to arise unless some common understanding is arrived at very shortly.

The Paper proper is followed by a number of appendixes, of which abstracts are given below.

APPENDIX I.

The first appendix deals with the single-phase system of the New York, New Haven & Hartford Railway, the various features of which have already been described and commented upon in THE ELECTRICIAN.*

During the past year, the electric service on this line has surpassed in efficiency all records previously obtained on this division with steam locomotives. The actual figures are given in Table I., which covers the movement of passenger trains over the 12 miles of third-rail operation and 21 miles of single-phase operation, for which 41

locomotives, that have been used from 22 to 33 months, were available. The early fears as to difficulties in commutation have been dispelled by the records of performances, many of the motors have operated over 100,000 miles without turning or even sandpapering the commutators, and the brushes show an average life of from 40,000 to 45,000 miles. The average number of miles run per locomotive delay during the year exceeds 12,000, equivalent to a dozen trips between New York and Chicago, or 30 trips between London and Glasgow. The locomotive delays (many of which only slightly exceeded one minute duration) include not only those from electrical causes, but from mechanical defects as well, such as loose tyres, burst air hose, hot journal boxes, frozen steam hose, &c. A comparatively large number of delays in December and January were due to the very severe weather and the unusual amount of snow and ice. These locomotives have been making regularly an average of about 4½ trips of 33 miles per day, hauling trains 25 to 50 per cent. heavier, or even more in the case of express trains, than the locomotives were guaranteed to handle. Most of the locomotives have run about 100,000 miles, but there is seldom more than one (which is 2½ per cent. of the whole number) out of service for repairs, a record said by the officials of the company to be much better than for the steam locomotives which were replaced. These officials also say that the cost of maintenance per mile and the number of miles run per electric locomotive are far more favourable than with steam locomotives, even with the present very short run of 33 miles.

The cost of maintenance of the distribution system is relatively small compared with that of the low-voltage third-rail system. The delays due to the transmission lines and overhead construction, though few in number, include those brought about by extraordinary conditions, such as steam from switch engines and by wrong operation of switches. The heaviest traffic on the New York division of the New Haven road, and the occasion on which delays would be most deplored, is on the day of the annual intercollegiate football game at New Haven. The service on this day for 1908 and 1909 was as follows :—

	1908.	1909.
Regular trains	128	126
Special trains	30	29
Total trains	158	155
Number of train delays	2	0
Total duration of delays	17 min.	

In considering the capability of the single-phase system for continuous performance, the record of the six single-phase locomotives in service at the St. Clair tunnel of the Grand Trunk Railway* is worthy of mention. These locomotives have now been running two years and have made about 70,000 miles each, averaging about 100 miles per day, or 25 trips of four miles. It has not been necessary to use a steam locomotive since the regular electric service was started (May, 1908), and during the last 12 months the service has been responsible for but one train delay, of eight minutes.

APPENDIX II.

Data on Electric Locomotives of American Design.

The locomotives on which data are given were built for heavy railway service. They are for passenger service and for combined passenger and freight, and include locomotives for direct current, three-phase current and single-phase alternating current, and others adapted for operation on either single-phase alternating current or direct current. A brief description of these locomotives follows, including mention of some of their notable features.

Locomotives of the Westinghouse Electric & Mfg. Co.—Referring to Table II., the first column covers locomotives built for the New York, New Haven & Hartford Railroad, for operation on their electrified zone between New York and New Haven. The electrical system demanded that the locomotives be capable of operation both on single phase and direct current. There are 41 of these locomotives in operation. A gearless concentric motor for each driving axle is mounted on a quill flexibly connected to the driving wheels. The deadweight on the axles is thus reduced to a minimum. The second column deals with locomotives built for the Grand Trunk Railway for operation in the St. Clair tunnel under the St. Clair River. These locomotives are designed for operation with single-phase current only. They are handling the entire freight and passenger traffic through the tunnel. The third column deals with locomotives built for the Pennsylvania Railroad for operation in their New York tunnel. They are for passenger service only, and operate on direct current at 600 volts on the conductor. The first locomotive has been run 17,000 miles on test. The centre of gravity of these locomotives is high, as the motor is mounted well above the driving axles. The transmission from motor to wheels is by cranks and connecting rods. These parts are protected from possible damage due to short-circuit by interposing between the armature and its shaft a friction clutch which will slip before damaging stresses are imposed on the transmission. The motors are the largest railway motors ever built and are provided with commutating poles, making possible the use of a shunted field control which is applied to these locomotives. The fourth column deals with a locomotive built for the New York, New Haven & Hartford Railroad for use in high-speed freight and medium-speed passenger service. It also is fitted for operation both with single-phase and direct current. It has been run approximately 3,000 miles in test service, actually hauling regular freight trains, including the steam locomotives, over the electrified section of the railroad on the normal schedules for the movement of these trains. A pinion at each end of the motor meshes with a flexible gear whose centre is rigidly secured to the quill surrounding the axle, the flexible gear overcoming the difficulties in securing tooth alignment and division of load which are liable to occur when rigid twin gears are used. It is the only electric locomotive equipped with spur-geared motors which are bolted rigidly to the spring-supported parts of the locomotive. Each driving wheel is driven through helical springs, the arrangement being such that the driving wheel has practically free vertical play. The locomotive has two trucks, the draw-bar pull being transmitted through the truck frames. The body is spring-mounted on friction plates in place of being carried on truck centre pins in the usual manner. It is an exceptionally easy riding machine with very low rolling friction. The performance has been satisfactory, and a speed of 40 miles per hour was attained on level track with a 1,600-ton train. The fifth column deals with a locomotive for the same railroad and service as that just described. The comparison between geared and connecting-rod motors for identical service is a very interesting feature of this development. The weights given in both the fourth and fifth columns are those on which locomotives of these types would generally be built. The actual locomotives are somewhat heavier, due to particular features of design not inherent in the type. The effect on the connecting rods and pins of the pulsating torque of a single-phase current is avoided by the introduction of a flexible connection between the armature and its shaft. This locomotive has not been tested. The last two locomotives were ordered by the New Haven road to demonstrate the practicability of electric traction for freight service and to assist in determining the most suitable kind or type of locomotive.

The first column of Table III. deals with locomotives built for the New York Central & Hudson River Railroad for operation on the electrified zone of the New York City terminal. Forty-seven of these locomotives are in use, the first having been put in operation in July, 1906. They are used for passenger service only, and operate on direct current at 600 volts. The mechanical equipment of this locomotive consists of a main driving wheel base with four driving axles and a four-wheel guiding truck at either end. The motor is of the bi-polar gearless type, the armature being mounted directly on the driving axle, and the mechanical structure of the locomotive forming a portion of the magnetic circuit of the motors. The characteristic feature of the locomotive is the simplicity of its electrical and mechanical construction, which contributes to its high efficiency and low maintenance cost. The second column of Table III. deals with locomotives built for operation at the Detroit River tunnel. These are to be used for both freight and passenger service between Detroit, Mich., and Windsor, Ont., and will be operated at 600 volts direct current. The running gear consists of two trucks connected together with a massive hinge so as to form a single articulated wheel base, and buffers carried on the outer end frames of the trucks. The motor is of the direct-current geared type with commutating poles and is interesting as the first application of the commutating pole motor to this class of service. Twin gearing is used between the motor and driving axle, and consists of a pinion at each end of the armature shaft and a corresponding gear on the axle. The use of twin gearing relieves the armature shaft of torsional strains and maintains the parallelism of the shaft and axle. Five of these locomotives have been built and are awaiting completion of the tunnel. While they are not in actual operation, extensive tests made on a test track in hauling and accelerating freight trains up to 1,500 tons in weight have proved that this type is very satisfactory for the service. The third column deals with locomotives built for the Baltimore & Ohio Railroad for operation of both freight and pasenger service through the Baltimore Belt Line tunnel. Two of these locomotives are in use and operate on direct current at 600 volts. The general design is similar to the Detroit tunnel locomotive described above and the same type of motors are used, but the motors are geared for higher speed in order to meet the speeds required by passenger service on the relatively lighter grades of the Baltimore tunnel. The fourth column deals with locomotives built for the operation of freight and passenger trains through the Cascade tunnel of the Great Northern Railway. These locomotives are designed for three-phase operation at 25 cycle

and 6,600 volts on the trolley. The mechanical structure consists of an articulated wheel base similar to that of the Detroit River tunnel locomotive described above. The motor is a three-phase induction motor with external secondary resistance and fitted with a gear at each end of the armature shaft. The service for which they are ultimately designed is the operation of a division 57 miles long with ruling gradients of 2·2 per cent. and an average grade of 1·55 per cent. Four of these locomotives are in service, and it may be of interest to note that they were involved in the disastrous avalanche of March 1, 1910, which swept through the electrified yards at Wellington, Wash. The fifth column deals with locomotives built for the Paris-Orleans Railway for use in hauling passenger trains from the Austerlitz station to the Quai d'Orsay. They are designed for operating on 600 volts direct current. These locomotives are historically of interest, the first one of them having been delivered in 1899, and 12 being now in service. Each locomotive has two independent trucks, each truck equipped with two geared motors, and carrying weight of cab and platform on the centre pin with draft gear and buffer attached to this platform. This represents a type of locomotive of which a large number have been built, and which has proved highly satisfactory for light and medium classes of service.

APPENDIX III.

Comparison of Systems of Electrification.

The salient features of the three systems of railway electrification are presented in a number of diagrams so arranged as to permit of a ready comparison between their essential characteristics, particularly in the circuits and apparatus which transmit the power from the power station to the locomotive. In thickly populated districts congested with traffic, the generating stations, of which there should be not less than two in order to minimise interruptions to traffic, should probably be located at junction points or places demanding the greatest power and at distances not exceeding 30 or 40 miles. With such a disposition of power houses, the overhead trolley wires on a single-phase system will usually be sufficient for the supply of current. In like manner, where the traffic is not so heavy, the power houses can be placed at greater distances, bearing in mind, however, that the increase in traffic may subsequently demand intermediate power houses or sub-stations. In cases where power stations are long distances apart, the single trolley wire should probably be supplemented by an additional circuit in order to guard aginst interruptions due to defects in the trolley wire, and to give a sufficient supply of power for any contingency.

Fig. 1 shows the comparative losses between the generators and the locomotives for each of the three systems, based on a class of service where the input to the locomotives by the several systems is practically the same. As some kinds of service render one type of motor with its auxiliary apparatus and control more efficient, while under other conditions it may be less efficient, this variable element has been eliminated by assuming the same power delivered to each locomotive as a basis for a general comparison of the transmission losses. The total height of each column in the diagram indicates the

Digitized by Google

total power delivered by the power house in the system designated. The height of the long portion at the lower part of each column indicates the amount of power which reaches the locomotive. The loss between power station and the locomotives is represented by the upper shaded areas. The respective losses in raising transformers, transmission line, lowering transformers, rotary converters and the contact line (comprising trolley or third-rail with track return) are segregated. It will be noted that the large losses in the rotary converters appear only in the direct-current system. The larger single-phase column shows the losses where the distances are such that it is necessary to use a transmission line and transformers. The smaller single-phase column represents the trolley wires connected to the

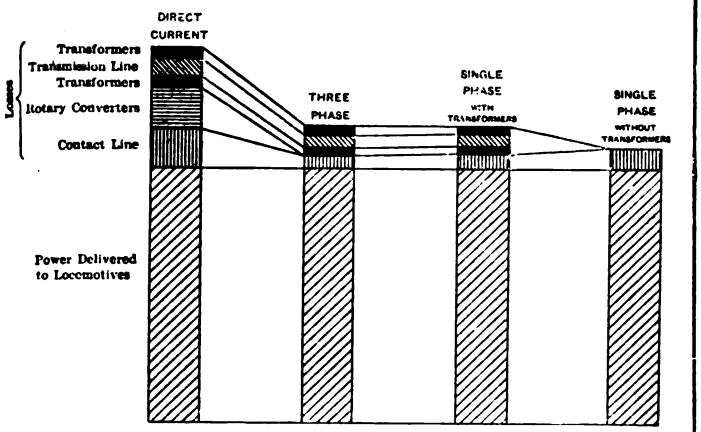

FIG. 1.—SHOWING COMPARATIVE LOSSES BETWEEN POWER HOUSE AND LOCOMOTIVES.

generators without any intervening transmission line or transformers. The loss of power between power house and locomotives is relatively small as compared with that in any of the other systems. This is the condition on the New York, New Haven & Hartford Railroad, where the power house is distant nearly 20 miles from one end of the line.

Fig. 2 shows the comparative estimates prepared a few months ago of first cost in a particular case for electrification by the direct-current system and by the single-phase system. In the preparation of these estimates the three-phase system was not called for and as no estimate covering it has been prepared, it is not included in the present

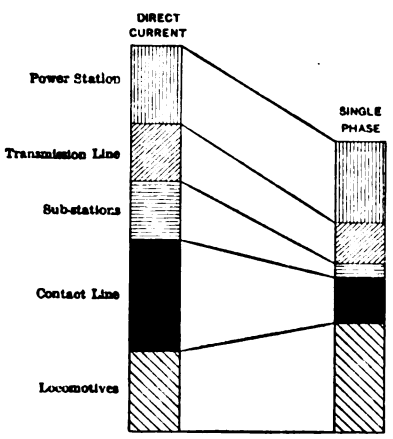

FIG. 2.—COMPARATIVE FIRST COSTS FOR DIRECT CURRENT AND SINGLE-PHASE SYSTEMS IN A PARTICULAR CASE OF A 100-MILE SERVICE.

comparison. The estimates cover a single track line 100 miles long involving both freight and passenger traffic in both through and local service and include 20 locomotives. The costs for power station include only the machinery and building and do not include cost of hydraulic development. It will be noted that the considerably less cost of the single-phase system in this case is due largely to the lower cost of contact line and sub-stations. Fig. 3 shows the comparative estimates of first cost for the three systems for a service on mountain gradients in a particular case involving the use of 12 locomotives. The total length of line is 32 miles, part of which is single track, part double track and part three tracks. In addition to the main line there is a large yard to be electrified, there being a total of 90 miles of single track. The location of the power station was fixed by non-electrical considerations. The distances were such that sub-stations were required when either direct current or three-phase current was assumed, but the entire system could be fed direct from the generators if single-phase current was used. It will be noted that in this case the omission of sub-stations and transmission effects a very considerable saving in favour of single phase as well as the usual large saving in cost of contact line effected by the use of this system. The cost of the part of the system between the power house and the locomotives in the direct-current system is nearly equal to the cost of both power house and locomotives. On the other hand, the cost of the single-phase contact line, the only intervening element between the power house and the locomotives, is less than one-half of the cost of the direct-current transmission and contact system.

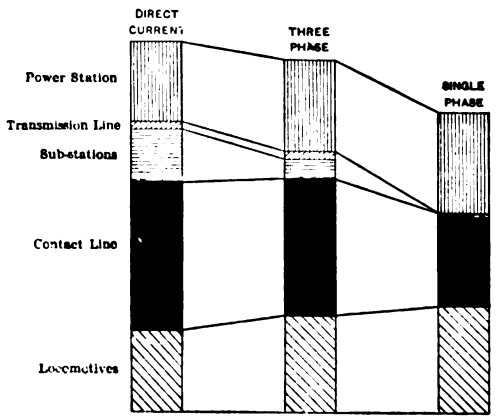

FIG. 3.—COMPARATIVE FIRST COSTS IN THE DIFFERENT SYSTEMS FOR A SPECIAL CASE OF PUSHER SERVICE.

Fig. 4 shows comparative operating costs for the three systems for the pusher service outlined in the preceding diagram of first costs. It should be noted that these costs do not include fixed charges. If fixed charges were included the difference in operating costs in favour of the single-phase system would be much more marked. In connection with this diagram it should be noted that sub-station attendance is required for the direct-current system only. The reason for the three-phase and single-phase systems being so nearly on a par is that this case is an ideal one for the application of the three-phase system since it involves constant-speed operation under constant-load conditions. It is notable, however, that even under these conditions the single-phase system shows somewhat lower operating costs than the three-phase system. The high operating cost with the direct-current system is seen to be due largely to the greater amount of power re-

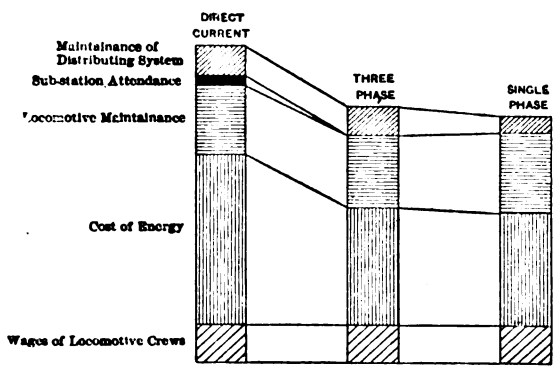

FIG. 4.—COMPARATIVE OPERATING COSTS IN THE DIFFERENT SYSTEMS IN A SPECIAL CASE OF PUSHER SERVICE.

quired for operation by this system on account of the large losses which occur between the power house and the locomotive in this system.

APPENDIX IV.

ELECTRIFIED STEAM ROADS AND ELECTRIC ROADS FOR TRUNK LINE SERVICE.

The accompanying tables give data upon many of the important railroads on which electricity is used in heavy railway service. Only such data are included as were conveniently available and such omissions or inaccuracies as may occur do not detract materially from the forceful presentation of the extent and character of the use which is now being made of electricity in railway service, The horse-power ratings of the various motor cars and locomotives are in general the nominal ratings for a short period, usually 1 hour, but as

ECONOMICS OF RAILWAY ELECTRIFICATION.*

BY WM. B. POTTER.

Summary.—The author, after a brief description of the different conditions met with in equipping a railway for continuous, single or three-phase current working, goes on to show how these conditions determine which should be employed and makes out a case for the 1,200 volt continuous-current system for interurban railways. Figures are given to show why this arrangement is the best, and why the single-phase system may come to be discarded in America for interurban work.

Much that has been written has treated the subject of electrification of steam railways from the general standpoint of averages, but, unfortunately, the economic application of electricity is not a subject for generalisation—unfortunately, because averages are convenient and usually available, but often lead to erroneous conclusions, either for or against electrification. It is a mistake to assume that the average of the expenses for the entire railroad represents the actual expense for the particular conditions usually existing on the division under consideration. Electrification, like any other engineering work, involves an investment against which there will be a fixed charge for interest and a liability of depreciation. The interest is a constant and permanent charge which must be met irrespective of any economy which may be secured by intelligent operation. The subject of depreciation is receiving more attention than formerly, the tendency having been to make the operating expenses cover this charge. However classified, the depreciation charge must be accounted for, and it is directly influenced by the character of the equipment with respect to reliability, durability and capacity to provide for future requirements.

The utilisation of higher trolley potentials, made possible with direct current by the development of the commutating-pole motor, and with alternating current by the development of the single-phase motor, the higher speeds of rotary apparatus in the sub-stations, and the development of the steam turbine, have effected a material reduction in the investment required and the cost of operation. The different methods of electrification applicable in any instance should be carefully analysed with regard to interest, depreciation and operating expense, and only the net result should be given consideration in determining the class of equipment. In this connection it is well to bear in mind that the expenditure is a lump sum which can be accurately determined, while depreciation and operating expense can only be approximated. Reference to the corresponding items of expense on railways operating under conditions comparable to those of the line to be electrified will supply the most reliable figures. Future traffic developments must not be overlooked, and the type of initial electrification should be selected with due regard to the ultimate requirements. There would, undoubtedly, be an advantage in having the character of the energy supplied to the contact conductor uniform, but this is out of the question on account of the great difference of specific conditions, such as congested urban or suburban service and comparatively infrequent trunk line train movements.

The development of apparatus for higher voltage direct current has so far increased its scope that direct current at either 600 volts or higher may be considered the most economical for city and interurban service, and for the electrification of steam railways where the density of traffic is sufficient to require a relatively large investment for rolling stock, as compared with that required for the secondary distribution system and the sub-station apparatus. Single-phase and three-phase rolling stock equipments are applicable only to exceptional conditions. The reason for this is the greater first cost of such equipments. This is especially true when comparing single-phase with direct current. The type of equipment used on the rolling stock may well be a more important factor in the economy of investment and operation than the scheme of power distribution.

In the selection of the electrical system best adapted to a particular set of conditions there are three items to be considered: (*a*) sub-stations, (*b*) contact conductors, (*c*) rolling stock. A comparison of these items determines the relative economic values of the systems. There are certain features under each of these items which may properly be examined. For trunk line service the values in Table I. will be found within reasonable limits for the usual requirements. From a level country to a limiting gradient of 1 or 1½ per cent. there will be little difference in the relative values of the systems. With steeper gradients the conditions will be more favourable for alter-

nating current. Heavy individual train units favour the alternating-current system with the exception of the locomotives; light trains or multiple-unit operation favour the direct-current system. Infrequent service with a relatively small number of locomotives favour the alternating current, frequent service the direct current. With an increase in the number of trains, the direct-current systems gain relatively faster than the alternating current in economy of operation, due to the relatively decreased sub-station operation, the increased sub-station efficiency and the lower cost of equipment maintenance. It is, therefore, well to consider what the ultimate traffic density may be and select the system best suited to meet these requirements. Variations in the distance between stops and the schedule will not affect the relative value of systems unless extreme requirements, such as high schedule speed with short runs, make the use of direct current imperative. For a similar character of service throughout, the railroad may be of any length without affecting the relative desirability of the various systems. What is suitable for the first 50 miles will be equally suitable for any extension. An examination of these variables will show that a change in the conditions to be met with radically changes the relative economic value of the systems of electrification.

The single-phase system, by reason of the apparent simplicity of its elements and the utilisation of a higher potential for the contact conductor than is possible with direct current, is admittedly very attractive. There is the other side of the question: that it is impossible to build a single-phase commutating motor comparable in first cost and maintenance with a direct-current motor. Over this subject of alternating-current single-phase versus direct-current systems there has been a great deal of controversy. It is the author's opinion that comparative results obtained up to the present time are in favour of direct current. Desirable as would be a standard system for all classes of service, we cannot hope to establish such a standard should it impose an additional expense without adequate return. A summing up of all the elements of each electrical system will generally lead to a definite showing of which system is most desirable to meet specific conditions. For trunk line service a higher potential than 600 volts will unquestionably be used; 1,200 volts direct current will prove economical in some cases, but a still higher voltage is required to provide economically for the heavier intermittent service. Whether this potential will be 1,800 or 2,400 volts direct current or 11,000 volts alternating current cannot be settled arbitrarily.

The application of single-phase to new projects in the United States has been practically abandoned, there having been but one or two new installations in the last three years. This arrested development of a system which for a short time held forth considerable promise has been brought about by a general recognition of its limitations. Experience has shown these to be excessive weight and cost of the rolling stock, the high cost of equipment maintenance, the increased power consumption, the rapid depreciation of the motor, the rapid depreciation of the car bodies and trucks, and the increased cost of maintaining the track and roadway. Moreover, it is recognised that any interurban road in the United States must be capable of operating over existing city tracks on 600 volt direct-current system, a condition which hampers the single-phase system on account of increased complications in the control system. For interurban railways a potential of 1,200 volt direct current has been selected, because with the motors wound for 600 volts the car may be operated at the same speed from either 600 or 1,200 volt trolley by connecting the motors all in parallel for 600 volt operation, and two in series with groups in parallel on a 1,200 volt section. To show clearly the relative merits of the systems, the authorities made an analysis of an interurban railroad 100 miles long with cars in each direction every hour. This condition represents practically the minimum car requirements in the United States, and is, therefore, favourable to the single phase. It is obvious that any increase in traffic density will be relatively more favourable to the direct-current system on account of the lower first cost of cars, lower car maintenance and relatively lower cost of sub-station operation. A comparison of the general data required for the operation of a typical urban line on the three systems is given in Tables II. to VII.

There will be an additional cost of operation and maintenance with the single-phase system for the items of track and roadway, due to additional weight of cars, car shop expenses in providing greater facilities for shop inspection and repairs, and greater skill in superintendence of equipment. In a number of instances this

Cost each sub-station complete	£4,800	£5,280	£2,000

LIBRARY OF THE UNIVERSITY OF CALIFORNIA

* Variation in cost of third rail due to different weights of rail which may be required. Variation in cost of overhead due to variation in the class of construction, such as with wooden poles or with steel bridges.

† Other weights of locomotives will cost more or less about in proportion to their weights. With gearless direct-current locomotives, the average efficiency of locomotive wheels to trolley is approximately 88 per cent.

* On 12 American single-phase interurban roads the average miles per day called for on the published time tables, divided by the number of cars owned, is 138; on four 1,200 volt roads which have been operating over a year this number is 237, the larger number of alternating-current cars being required on account of the fact that a greater number are necessarily held in the barn for inspection and maintenance purposes. This explains why in the table above 18 alternating-current cars are assumed and 15 direct-current cars.

Operation and maintenance	19,160	16,460	20,800
Annual cost	£35,400	£30,580	£38,480
Based on 1,095,000 car-miles per year, additional annual charge per car-mile above the cost for 1,200 volts, pence	1·05	..	1·8

has been found to amount to several pence per car-mile. A conservative estimate would require at least 0·5d. per car-mile to be added for these items. The comparison in Table VII. brings out the fact that even for conditions selected as favourable to the single-phase system the 600 volt direct-current system is the more economical considering operation, maintenance and fixed charges. An examination of the elements which enter into the first cost and operation of a system will show at once that as the density of traffic increases there is a rapid gain in the relative advantage of the direct-current over the single-phase system.

The saving effected by the 1,200 volt direct-current system is so marked that a great increase in the adoption of this potential for this class of interurban railroading may be anticipated, and on the other hand it will not be surprising if the single-phase interurban system is entirely discarded in America, unless some marked improvement is made in the art and a more economical equipment made available. There is no question regarding the mere movement of trains by any particular system—this may be taken for granted. The study of electrification is really a problem in economic engineering, and not simply a technical problem.

Reliability of operation is of the greatest importance, not only to the public, but to the operating company, and in this respect the electric motor, with its simpler construction, even though the general service is supplied from a central power station, has proved its superiority over the steam locomotive. Except in the case of some extraordinary accident, the power station, sub-stations and transmission line, in their entirety, are rarely rendered inoperative. The liability to interruption is principally centred in the equipment of the rolling stock, and for this reason the mechanical and electrical design of the motors, control and equipment devices should receive careful consideration. The electrical equipment of motor cars and locomotive is exposed to a large extent to dirt, water and snow, and not being particularly convenient for inspection, it usually receives less attention than the apparatus in the power station and sub-stations. It is the custom on many roads to give the equipments a regular inspection once in 1,000 or 1,500 miles, depending on experience, and to dismantle them for a thorough overhauling once a year. The character of the rolling stock equipment is a factor of far more importance to the reliability of the service than is often appreciated.

The steam locomotive has been brought to its present state of development through many years of experience. It is an exponent of the highest type of mechanical design, and, notwithstanding its limitations, is remarkably efficient as a source of power. During the past 20 years the power of the steam locomotive has been practically doubled, but the demand to-day is for still greater power. The multiple-unit idea, to which electric service is so well adapted, was utilised in the design of the Mallet type of steam locomotive, where the driving engines of two practically separate locomotives are supplied with steam from a single boiler. Mallet locomotives have been built having a weight of 441,000 lb. on the drivers, the boiler having over 5,800 sq. ft. of heating surface and a grate area of 100 sq. ft. To fire properly a locomotive of this capacity is difficult, and, unlike the electric locomotive, its effectiveness depends on the steam from its own particular boiler. With existing road clearances, the steam locomotive unit, controlled by a single engineer, seems to have reached nearly the limit of power. The power of a steam locomotive being limited by the capacity of its boiler, an increase in speed can be secured only by a proportional reduction in tractive force. The electric locomotive, on the other hand, is supplied with practically unlimited power from an independent power station, and can maintain a speed and tractive force that would be impracticable with a steam locomotive. The application of electric locomotives to passenger and freight service will result in faster schedules with equal or even heavier trains than are at present handled by steam locomotives.

Since the electric locomotive is equipped with a number of independent motor units, controlled by one engineer from a single master controller, it makes no difference, considering the complete locomotive as a machine, whether it be built as a single unit or as two or three units having the same total weight on the drivers. For convenience in operation and repairs, it is probable that a single electric locomotive unit will be limited to a weight between 200,000 lb. and 300,000 lb. on the drivers, even when built for the heaviest service. There are electric locomotives now under consideration which as single units will exert a maximum tractive effort of 90,000 lb., and which will be capable of maintaining a tractive effort of 35,000 lb. at a speed of 30 miles per hour.

Many of the terminal and tunnel electrifications have been brought about from the desire to do away with the danger and nuisance caused by smoke and gas. The elimination of smoke has also an economic aspect in the electrification of terminal stations in per-

Digitized by Google

mitting material improvement in the character and value of railway buildings. The Quai d'Orsay terminal of the Paris–Orleans Railway in Paris, which has been in operation since May, 1900, was the first instance where a steam railway profited by this feature of electrification.

The enhanced value of railway buildings is seen to a marked degree when terminals are electrified in large cities in which land values are high. The fact that electric operation will permit platforms on two or more levels adds greatly to the capacity of the station, or, conversely, decreases the land area required for given traffic facilities. In the case of the New York Central terminal in New York City there will be two levels of platforms, the entire suburban facilities being placed below those of the main line. The Pennsylvania terminal in New York is another instance of station design affording facilities for handling traffic that would be impossible under steam operation.

The electric locomotive is well adapted for the handling of trains where the character of the service will not permit the operation of individually equipped cars. Where the service is self-contained, individually equipped motor cars, operated in trains with multiple-unit control, are recognised as providing for the most efficient handling of traffic.

Economy in operation will be secured by proportioning the number of cars in a train to the traffic required during different hours of the day. The patronage on which the gross receipts depend will be much encouraged by providing a service with short intervals between trains. In the study of any scheme of transportation, due regard should be given, not only to economical operation, but also to the method of handling which will ensure the maximum gross receipts.

THE COST OF ELECTRICALLY-PROPELLED SUBURBAN TRAINS.*

BY H. M. HOBART.

Summary.—In comparing the cost of electrically-operated suburban trains the chief items which differ from those of steam locomotive methods are the cost of the energy, the annual charges for the rolling stock and the cost of the distributing system. For the sake of argument, the last of these is taken to be independent of the particular electrical system used, and calculations are made to determine the relative costs of the single-phase and continuous-current methods. Actual operating railways are taken, and it is shown that for suburban passenger traffic the continuous-current system has decided commercial advantages.

The commercial aspects of applying electricity to the propulsion of suburban trains involve many factors, and the thorough investigation of any one of these factors requires careful study. In the present paper the author's aim is to focus attention chiefly on the rolling stock, but it must not be inferred that he implies that the other factors affecting the total cost are of minor importance. It is absolutely insufficient to approach the subject of railway electrification from the standpoint that it resolves itself into a mere question of contrasting electric propulsion with steam locomotive propulsion. The reason for delay in replacing steam locomotive methods by electric propulsion is, so far as concerns the suburban passenger traffic, nearly always related to the large capital expenditure involved in effecting the change. For not applying electrical methods to other classes of railway traffic there is, so far as relates to Great Britain, the best of all reasons—namely, that steam is, at present, in almost all instances, more economical.†

In view of the circumstances, the question of the relative cost of various electrical systems of operating suburban lines becomes one of great importance. The two systems which are, at the present time, chiefly commanding attention are the systems employing on the trains continuous-current motors and single-phase motors respectively, and, with a view to concentration, only these two systems will be taken into account. For the particular investigation which constitutes the object of this paper, it will conduce to clearness to break away completely from these conventional methods of analysing costs.

In view of the circumstances that any single railway almost always traverses districts served by many different electricity supply companies, it is highly probable that for some long time to come, at any rate, a railway would, in many cases, be best serving its own interests by purchasing its electricity from electricity supply companies and municipal electricity supply undertakings. The author will, therefore, assume that the railway not only purchases its electricity from independent undertakings, but that it looks to these independent undertakings to provide all transmission lines from the points where the electricity is "generated," and also to provide all the sub-stations, thus delivering the electricity at the required points on the railway company's premises in the form in which it is collected by the trolley bows or rail shoes carried by the train. The sub-stations are thus the property of the electricity supply company. The railway is, however, the proprietor of all the cables and structures intermediary between the sub-stations and the trains. The price charged by the independent electricity supply undertakings will be for the electricity in the form in which it is delivered from the sub-stations, and owing to the greater cost and lower efficiency of the sub-stations when supplying continuous electricity, the railway will be obliged to pay a higher price for a given quantity of electricity when it is in the continuous form than when it is in the single-phase form. Prices arrived at by experience on a large scale are now quite well agreed upon for electricity in these two forms. While these prices vary greatly according to the price of fuel and various factors of like nature and while they also vary greatly with the nature of the load, they can nevertheless be estimated with certainty in any particular case.

Thus, so far as the outlay for electrical apparatus and equipment is concerned, this method of comparison leads us to the definite proposition of estimating the cost of the rolling stock and the cost of the structures along the line, intermediary between the sub-stations and the trains. While the cost of these structures has, up to the present, been higher with the single-phase than with the continuous system, the author does not propose in this Paper to discuss these differences, but he will, on the contrary, assume that the outlay for this portion of the work is the same for both systems. As to the cost of the trains estimates for each system will be made, since in this respect the two systems differ greatly from one another.

To fix ideas, the author will confine his comparisons chiefly to trains consisting of three double-bogie coaches. It is well known that, under reasonably favourable conditions, such trains usually yield gross receipts of some 40d. to 60d. per train-mile. The cost of the electricity required for the propulsion of the trains, together with reasonable estimates for the capital charges for the trains, including the outlay for their depreciation, repairs and renewals, make up an aggregate per train-mile which is usually of the order of from 35 to 40 per cent. of the amount of the gross receipts. Into the disposition of the remainder of the gross receipts it is not proposed to enter, since (taking the electrical structures along the line, that is, the equipment intermediary between the sub-stations and the trains, as representing the same outlay, irrespective of the particular system of electric traction adopted) the disposition of this remainder will be substantially the same, whichever system is employed, and hence does not materially affect the results in a comparison of systems. For high speeds with frequent stops, both the single-phase system and the continuous system have long been recognised to be adequate as regards their engineering features, but the former entails distinctly greater outlay and distinctly less net earnings. With decreasing speed for a given distance between stops, or with increasing distance between stops for a given speed, the disabilities of the single-phase system become less acute.

The severity of a train service is a function of the schedule speed and of the distance between stops. For a very severe service, many of the train axles are often driven by motors, while for more moderate services it suffices to concentrate the driving power upon but a few of the axles. In eliminating the locomotive and placing the motors under the passenger coaches, the space available for the motors is rather restricted, and the plan of distributing several relatively small motors on several axles is more often a consequence of this space limitation than of any regard for obtaining greater tractive effort by the greater total weight on the driven axles. Although this latter object is always kept in view, it may be said that even the high accelerations employed on electric railways rarely require so great a sub-division of the driving power as is, for severe services, usually resorted to, owing to the space limitations.

The author proposes first to analyse the design and performance of two 150 ft. trains designed for about the same "average output," and similar as regards the capacity and distribution of the electrical equipment. In the two 150 ft. trains which have been selected for this analysis, only two motors are employed, and these drive two of the four axles of a motor coach. Each of these 150 ft. trains comprises three 50 ft. coaches, of which one is a motor coach and the

* Abstract.

† This is usually the case. The presence of frequent tunnels may afford the chief reason for adopting electricity on a given section, owing to the elimination of smoke and steam. But if it is proposed to employ a bare 6,000-volt overhead conductor for supplying the trains, the presence of tunnels of small dimensions may afford the most cogent reason for adhering to the steam locomotive. Heavy grades are much more readily negotiated by electrically-propelled trains, and consequently, for mountain lines there is an additional incentive for substituting electrical propulsion for steam locomotive methods.

Digitized by Google

other two are trailer coaches. Thus out of the 12 axles, only two are driven. The first of these two trains is a type designated A, which is employed on the Piccadilly Tube Railway in London and weighs 61 tons; the second is a type designated C, which is employed on the Heysham, Morecambe and Lancaster Branch of the Midland Railway and weighs 77 tons. The service for which the 61-ton Piccadilly Tube train is employed requires a schedule speed of 16·4 miles per hour, and the runs are of an average distance of 0·45 mile between stations. The 77-ton Heysham train has a schedule speed of some 31 miles per hour, and there is an average distance of 4 miles between stations. It might appear at first sight that these two services are not comparable, but brief calculations show that the average output to the axles is just about the same in the two cases. Furthermore, the average efficiencies of the two electrical equipments do not differ by more than 5 per cent. at the outside. This is also the case as regards the efficiencies in the two cases of 180 ft. trains, examined in a later section of this Paper, and with a view to avoiding a discussion of so unessential a matter as a few per cent. difference in efficiency, the author has throughout his comparisons employed the mean value of 70 per cent. His examinations indicate that in no one of the four cases (that is, the two 150 ft. trains and the two 180 ft. trains) is the average efficiency of the electrical equipment on the train for the services for which the trains are employed greater than 72 per cent. or less than 68 per cent.; consequently the employment throughout of the value of 70 per cent. is amply exact and is in the interests of simplicity. The two particular instances of two-motor 150 ft. trains have been taken because precise data of their design and performance are available, and because, while they are equipped for about the same average output, the one train carries continuous-electricity equipment and the other carries single-phase equipment. For the 61-ton Piccadilly train the output of the equipment averaged over the entire time, including stops, is 87 H.P.; for the 77-ton Heysham train the corresponding figure is 90 H.P. The total weight of the electrical equipment in the two cases is 8 tons* and 14·9 tons respectively. In each case the service is that for which the equipment was selected, and in each case the ultimate temperature rise in regular service is of moderate amount. The calculations for these two trains are set forth in parallel columns in Table I.

Ratio of these two average outputs per ton of electrical equipment ...	$\frac{10·9}{6·04} = 1·8$	

Having now examined two 150 ft. trains composed of one motor coach and two trailers, let us turn our attention to two trains for more severe services. The two trains which the author has selected for his purpose are each 180 ft. in length and are each composed of two motor coaches and one trailer coach. Each coach is 60 ft. in length. Each motor coach is equipped with four motors, making up a total of eight motors per train. Thus eight of the 12 axles of the train are driven by motors, whereas in the two former trains only two out of the 12 axles were driven. The first of these two 180 ft. trains is of a type which may be designated as B, and which is employed on the Southport line, and the second, which may be designated as D, is one of the trains now operating on the South London Elevated Railway. The trains are thus somewhat longer and are much heavier than those which we have examined before. The weights of these two 180 ft. trains are respectively 118 tons and 138 tons. The Southport train runs at a schedule speed of 30 miles per hour, and the average distance between stations is 1·32 miles. The South London Elevated train, which will be designated the S.L.E. train, runs at a schedule speed of 22 miles per hour, and the average distance between stations is 0·88 mile. The striking similarity of these trains as regards their length (180 ft.), their seating capacity and the proportion of motor and trailer coaches, has led to the establishment of comparisons between them. But these comparisons have usually been of an utterly superficial nature. It has been said that since in the case of the Southport train the stops are less frequent and the speed is higher, the severity of the service is substantially the same as in the case of the S.L.E. train, and it has been assumed, though altogether incorrectly, that the more frequent stops in the case of the S.L.E. train offset the greater speed in the case of the Southport train. The author has, however, pointed out on various occasions that this is not the case. On the contrary, the power which is required at the axles in the case of the Southport 118-ton train is 42 per cent. greater than the power which is required at the axles for the S.L.E. 138-ton train, notwithstanding the 18 per cent. greater weight of the latter train, and the power required at the axles per ton of total train weight, is no less than 65 per cent. greater for the Southport service than for the S.L.E. service.

The service performed by the Southport 118-ton train requires of the electrical equipment an output to the axles, averaged over the entire run, of 319 H.P., whereas the relatively much less severe service of the S.L.E. 138-ton train requires an output to the axles of only 225 H.P. The weights of the electrical equipments in the two cases are, however, 30 and 44 tons respectively. The average horse-power output to the axles per ton of electrical equipment, works out respectively at 10·6 H.P. for the Southport train and 5·12 H.P. for the S.L.E. train. In Table II. these calculations are set forth in parallel columns.

Table II.

—	Southport train.	South London Elevated train.
Number of motor coaches	2

Average input per train ($a \times b$) ... kw.	340	240
Average output from motors to axles (taking average efficiency of electrical equipment at 70 per cent.) ... H.P.	319	225
Weight of electrical equipment ... tons	30	44
Average output per ton of elec. equipment ... H.P.	10·6	5·12
Ratio of these two average outputs per ton of electrical equipment ...	$\frac{10·6}{5·12} = 2·07$	

It will be observed that the average output per ton of electrical equipment varies greatly in the four cases which we have examined, and questions naturally arise as to the cause of these great variations. It might be suggested that the variations are attributable to diverging views as to correct methods of design. As it happens, however, the equipments were supplied by four different manufacturers who are amongst the half-dozen firms who probably have the greatest experience in the manufacture of electric railway equipments, and who are all on a substantially equal footing as regards ability to produce the best, lightest and cheapest apparatus for the purpose in view. Consequently, we must seek some other explanation for the striking difference in the results. The two first results are within 3 per cent. of each other and the two last results are within 18 per cent. of each other. The mean of the first two results is 10·8 H.P. per ton, and the mean of the last two results is 5·6 H.P. per ton. These two values have the ratio 1·93 : 1·00. The reason for this difference in weight of about 2 to 1 is that in the first two cases (that is, the Piccadilly Tube 61-ton train and the Southport 118-ton train) the equipments are designed for and operated with continuous electricity, whereas the last two cases (the Heysham 77-ton train and the S.L.E. 138-ton train) have equipments designed for and operated with single-phase electricity.

* This estimate of 8 tons is somewhat in excess of the weight usually assigned to the equipment of the Piccadilly Tube trains. The figure usually given is 7·3 tons, but the author prefers to take 8 tons since the weight of auxiliary equipment tends gradually to increase in successive installations. This is because with the development of electrical methods, refinements are introduced which were not deemed necessary in the earlier work. This estimate of 8 tons is ample to cover air-compressors and governor, all cables, slate switch-panels, collecting shoes, and shoe beams for both trucks of the motor coach, steel-tubing bolts, cleats, &c. The estimate of 14·9 tons is for the Siemens Co.'s equipment as installed on the Heysham train.

Digitized by Google

As rough, but representative, values, we may take it that for a train equipped with continuous apparatus, the electrical equipment may, in actual service, and for approved overload and heating limits, be loaded up to an average output of 11 H.P. per ton weight of the equipment, whereas single-phase equipments can only be worked up to an average output of 6 H.P. per ton. It has been asserted that notwithstanding that the single-phase equipment for a train required to perform a given service weighs twice as much per horse-power as the corresponding continuous equipment, this does not seriously affect the total train weight, since the weight of the electrical equipment constitutes (it is alleged) only a small part of the total weight of the train. Let us investigate this assertion. In Table III. are given the total train weights, the weight of the electrical equipment, and the percentage which the weight of the electrical equipment constitutes of the total train weight.

Table III.

System.	Designation of train.	Railway.	Length of train.	Total train weight	Weight of electrical equipment.	Percentage which weight of electrical equipment constitutes of the total weight of the train.
			Feet.	Tons.	Tons.	Per cent.
Continuous.	A	Piccadilly	150	61	8·0	13·1
Continuous.	B	Southport	180	118	30·0	25·4
Single-phase	C	Heysham	150	77	14·9	19·3
Single-phase	D	S.L.E.	180	138	44·0	32·0

Comparing the 180 ft. trains, that is, trains B and D, we have seen that the Southport service is much the more severe, yet the electrical equipment of the Southport train only amounts to 25·4 per cent. of the total weight, as against 32 per cent. of the total weight for the much less severe S.L.E. service. It should be of interest to ascertain how a train of the "D" type would require to be modified in order to be suitable to perform the "B" service. This and subsequent calculations will be simplified by first working out, for all the trains, the average horse-power per ton weight of train required for the respective services. This is done in Table IV.

The values in the lowest horizontal line of Table IV. are the real criteria of the severity of the service, and we see that the Southport service requires 65 per cent. more average power per ton weight of train than is required for the S.L.E. service. The values in the lower line of Table IV. are (since the efficiency is the same) independent of whether single-phase or continuous apparatus is employed. For the Southport service there must be provided 2·7 H.P. per ton weight of train. Since we have seen that, with single-phase equipment, we obtain 6 H.P. per ton of equipment, we shall require 0·45 ton of electrical equipment for every ton of total weight of train. Thus 45 per cent. of the weight of the train will consist of electrical equipment.

Table IV.

System	Continuous.		Single-phase.	
Designation of train	A	B	C	D
Road	Piccadilly	Southport	Heysham	S.L.E.
Length of train.....feet	150	180	150	180
Weight of train .....tons	61	118	77	138
Av. output during service H.P	87	319	90	225
Do. per ton weight of train H.P	1·42	2·70	1·17	1·63

The motor coaches on the S.L.E. line weigh 54 tons each. Of this 54 tons weight of one of these motor coaches, only 22 tons, that is, only 41 per cent. of the total weight of the motor coach, is electrical equipment, and consequently the motor coach which is at present running the S.L.E. service, even with its motors re-wound for the required speed, would not have sufficient capacity (leaving the same margin as on the present S.L.E. service) to accomplish the Southport schedule with the same heating of the electrical equipment as in the S.L.E. service, much less could a train composed of two motor coaches and one trailer accomplish this schedule with normal heating and with appropriate overload capacity. In order to work the S.L.E. 180 ft. train to the Southport schedule, its electrical equipment must be considerably increased in weight. Let W equal the total weight of the S.L.E. 180 ft. train, in tons, when reinforced to render it adequate for the Southport service. Then the electrical equipment must weigh 0·45 W. The weight of the S.L.E. 180 ft. train, exclusive of the electrical equipment, is $138-44=94$ tons. Its revised weight, when provided with an equipment enabling it to conform to the Southport service, will consequently be

$$W=0{\cdot}45\times W+94.$$

Therefore we have $W=171$ tons.

The weight of the electrical equipment must thus be 77 tons, and the electrical equipment will be capable of delivering an average output of 462 H.P. Thus the equipment of the S.L.E. train must be increased, as regards its average output, from the 225 H.P. which sufficed for the S.L.E. service, up to the 462 H.P. necessary in order that it may accomplish the Southport service. This is an increase of 105 per cent. The revised S.L.E. train requires to have 462 H.P. average capacity as against the Southport train's 319 H.P. average capacity, an excess of 45 per cent. This further 45 per cent. serves no more useful purpose than to carry over the route the increased weight of expensive electrical equipment made necessary by the use of the single-phase system. The revised S.L.E. train weighs 171 tons, as against the Southport train's weight of only 118 tons. Thus the result is, that while both trains have the same length of 180 ft., the S.L.E. train, when altered to be adequate to perform the Southport service, weighs 45 per cent. more than the Southport train. Moreover, the revised three-coach single-phase train for the Southport service would have to consist of three motor coaches, in place of the two motor coaches and one trailer which sufficed to carry the necessary single-phase equipment to perform the S.L.E. service.

Let us next reverse the above process and adapt the Southport train to the S.L.E. service of 22 miles per hour and one stop every 0·88 mile. This service requires, as seen from Table IV., only 1·63 H.P. per ton of total weight of train. 1·63 H.P. of continuous equipment weighs only 0·148 ton. Consequently out of each ton of total train weight, only 14·8 per cent. will consist of electrical equipment as against the 32 per cent. seen from Table III. to be required when the S.L.E. service is provided by a train equipped with single-phase apparatus. Let us again represent by W the total train weight in tons. Then the weight of the electrical equipment in tons amounts to $0{\cdot}148\times W$. The weight of the Southport train, exclusive of the electrical equipment, is 88 tons. Consequently $W=0{\cdot}148\times W+88=103$ tons. The weight of the electrical equipment of the revised Southport train, that is, of the continuous train capable of working to the relatively moderate S.L.E. service, is only 15·3 tons, or only 51 per cent. of the 30 tons weight of the electrical equipment required for the Southport train performing the severe Southport service. Obviously then, were we to operate a 180 ft. train to the S.L.E. schedule, employing continuous equipment instead of single-phase equipment, we should not require two motor coaches, but we should make up our three-coach train of one motor coach and two trailers. The continuous equipment thus weighs only 15·3 tons, or only 34·8 per cent. of the 44 tons required for the single-phase train of equal length. It is interesting to note that this continuous-electricity train operating on the S.L.E. service is only required to give an average output of 168·5 H.P., which amounts to only 75 per cent. of the average output required of the motors on the single-phase 138-ton S.L.E. train.

Table V.

Electrical equipment of one train.	Weight.	Cost per ton.	Total cost.
	Tons.	£	£
Continuous train for Southport service.....	30·0	125	3,750
Continuous train for S.L.E. service	15·3		1,910
Single-phase train for Southport service....	77·0		9,630
Single-phase train for S.L.E. service.....	44·0		5,500

A rough but thoroughly representative figure for the cost of continuous equipment for railways is £125 per ton. Single-phase equipment at present costs decidedly more, but for the purposes of this investigation the author will take the cost of the electrical equipment, irrespective of whether it is continuous or single-phase, at £125 per ton. Thus for the four trains under consideration, the costs for the electrical equipment work out as shown in Table V.

The weight of each motor truck, including truck frames, wheels, axles, brake rigging, &c., will be taken at 6·5 tons, the weight of each trailing truck at 5·5 tons. In both cases, the cost of the complete trucks will be taken at £22 per ton.

The total costs of the four trains are made up as shown in Table VI.

Since these trains have a seating capacity of, roughly, one seat per foot, the two lower horizontal lines in Table VI. also give a fair representation of the relative costs and weights per seat. We see that for so severe a service as that at Southport, the cost of a single-phase train works out to be 65 per cent. greater per foot of length than is the cost of a continuous train. For the much more moderate service of the S.L.E. line, the excess cost of the single-phase train per foot of length is only 51 per cent., and the percentage continues to fall with every amelioration in the severity of the service.

It is usually preferable to reduce weights and costs to the basis of the weight and cost per foot length of train instead of per seat. Otherwise it is very difficult to effect comparisons, for not only have we to take into account the varying composition of trains as regards

first and third-class carriages, but there is the further consideration that the policy of railways differs considerably as to the floor space and elbow room which are allotted to each passenger. Since, however, the average value of the seats per foot for representative passenger trains of mixed composition rarely varies much from unity, the values of the weight and cost per foot enable us readily to make mental calculations, as occasion requires, of the corresponding weights and costs per seat. It is preferable, in all cases, to take the weights of the trains themselves, and to leave out of consideration the weights of the passengers.

We have now deduced fairly definite values for the weights and costs of the rolling stock. The component of the total cost represented by the electricity consumed by the train is also fairly definite for a given service. The consumption at the train is for a given service about the same per ton-mile whether the electrical equipment be continuous or single phase. The values in Table VII. afford a reasonable basis for estimating the consumption at the train per ton-mile of actual performance, when the train is handled by a fairly experienced driver, and when it is running strictly to its time-table, and over a well-built, fairly straight and level permanent way. Although quite practicable variations in the acceleration and braking may easily occasion variations of 10 per cent. or more in the energy consumption at the train, nevertheless the values in Table VII. are representative of the customary results obtained under the conditions stated.

In the case of passenger trains it is preferable for uniformity's sake to estimate the ton-mileage on the basis of the weight of the empty train. The unrecorded ton-mileage corresponding to the weight of the passengers carried, together with that corresponding to shunting operations and other non-remunerative running, as well as the increased consumption on occasions when the time-table is disarranged, will usually bring up the total consumption at the train to a value some 30 per cent. greater than the values given in Table VII. This increase is only in small part due to the weight of the passengers, since with average loads the weight of the passengers rarely increases the weight of the train by more than some 5 to 6 per cent. In the following estimates the author will take the consumption of electricity at the train as 1·30 times the values in Table VII. To simplify the investigation he will not go into the question of whether the railway provides its own generating plant or purchases the electricity from a supply company; but he will merely assume that the electricity is obtained at a total cost of 0·65d. per kilowatt-hour as delivered to the sub-stations. Owing to the greater loss in transformation at the sub-stations and the greater cost of the sub-stations in the continuous, as contrasted with the single-phase system, he will take the cost of the electricity as delivered from the sub-stations at 0·70d. per kilowatt-hour for the single-phase system and at 0·87d. per kilowatt-hour for the continuous system. These amounts cover all outlays, both capital and operating, up to the outgoing cables from the sub-stations. The losses in the transmission system from the sub-stations to the trains are of but small amount in either system. To allow for them he will take the cost of the electricity delivered at the trains as 0·72d. per kilowatt-hour for the single-phase system, and 0·90d. per kilowatt-hour for the continuous system. These last increases in the cost simply allow for the electricity wasted in the process of being conveyed from the sub-stations to the trains, and do not allow for the capital and maintenance charges for the cables and the conductor rails or overhead structures by means of which the electricity is conveyed from the sub-stations to the trains. The two figures of 0·72d. and 0·90d. per kilowatt-hour respectively are thoroughly representative as regards their relative values though their actual values, while representative, will vary considerably according to many local circumstances.

Furthermore, these values are only applicable for the conditions of a suburban service of passenger trains where the trains in each direction run, as an average, at intervals of some 12 to 15 minutes during some 16 to 20 hours per day. For a less intense service, the price for continuous electricity will exceed that for single-phase electricity by a greater percentage, since the cost of the sub-stations will constitute a larger item, and the "all-day" efficiency of the sub-stations will be less. If, on the contrary, the trains run at intervals of only some three to six minutes, then also the relative figures of 0·72d. and 0·90d. at the trains are not applicable; 0·69d. for the single-phase system and 0·83d. for the continuous system would then be more appropriate, the latter in this case exceeding the former by only 20 per cent. as against 25 per cent. in the case of the 12 to 15 minutes' service. This is because, while the cost of the electricity, as delivered at the trains, in the case of both systems, decreases with the intensity of traffic, the decrease is a greater amount for the continuous system, owing to the better load factor at the sub-stations and the consequent considerable reduction in the capital charges and operating expenses of the sub-stations. For his further comparisons, however, the author will take the figures of 0·72d. for the single-phase system and 0·90d. for the continuous system for the cost of electricity per kilowatt-hour delivered at the trains.

With these data, we may now estimate the cost of the electricity consumed by 180 ft. trains operating in the Southport service (as an instance of a severe service) and in the S.L.E. service (as an instance of a much more moderate service). The price actually paid for the electricity for the S.L.E. trains is, at present, decidedly higher than the figures here taken, but the fairly high price in that instance is probably, to some extent, incidental to the experimental nature of the undertaking at this stage. It is well known that in most districts there would, under the conditions already indicated, be reasonable profit in supplying railways with electricity at the prices stated, and hence it is only on the basis of such prices that the comparisons will lead to useful results. To fix ideas, it can be taken that the author's figures relate to a hypothetical road so situated that his prices for electricity are applicable and have been quoted, and that the engineers of this road are engaged in determining whether to use the continuous or the single-phase system, and the schedule speed to be provided on various sections of line with various distances between stations.

Out of the 8,760 hours in the year, it is rarely practicable, on other than tube railways or railways providing the class of service associated with tube railways, to attain (for suburban passenger trains) to much more than 2,000 hours of actual service on the line. Usually the figure is decidedly less than 2,000 hours. For a schedule speed of 30 miles per hour, the profitable mileage per train per annum, on the basis of 2,000 hours, works out at 60,000 miles, and for a schedule speed of 22 miles per hour it works out at 44,000 miles. Under the conditions of actual service, there will not be so much difference as this between the annual average mileage per train for these two schedules. The more the service conforms to the conditions of a tramway service, the more uniform and continuous will be the sequence of trains; consequently, for the 22 miles per hour case the author will take the annual average mileage per train at 48,000 miles instead of the above 44,000 miles, and for the 30 miles per hour case he will take the annual average mileage at 54,000 miles instead of the above 60,000 miles. The total cost of electricity per annum per train is obtained as shown in Table VIII.

For comparative purposes the rough figure of 15 per cent. of the cost of the rolling stock is taken as the annual charges for interest, depreciation, repairs and renewals. He will term these the annual charges for capital, depreciation, repairs and renewals per train, and as a check to indicate their general reasonableness, he will in Table IX. show the corresponding values per train-mile.

Amongst the many and large remaining costs, there are none in which the adoption of the continuous system will entail greater costs per train than are incurred with the single-phase system.

It is well known that the gross receipts for three-coach trains on services of this character are usually of the order of from 40d. to 60d. per train-mile. Let us fix our attention on a case where the gross receipts are 50d. per train-mile. It is evident from the results in the lowest horizontal line of Table IX. that in such a case, whatever be the net profits, they will be less if the single-phase system is used than if the continuous system is used. The percentage of the gross receipts which could be set aside as profits would, for the 30 miles per hour one-shop per 1·32 mile service, be 12·45 per cent. greater with the continuous than with the single-phase system. For the 22 miles per hour one stop per 0·88 mile service they would still be greater by 6·7 per cent. It is common knowledge that suburban traffic is at present very unremunerative, although this is not always obvious from balance-sheets where the profits shown are usually very largely from main-line and goods traffic. Confining our attention to the suburban traffic, it appears that while there may be a few services in which the margin in favour of electrification is great enough to stand the higher cost of the single-phase system, there are many in which the great difference which the author has shown as existing between the two systems would make all the difference between commercial success and commercial failure.

The subject is a large one with many important aspects. This investigation, however, clearly shows that the selection of the electrical system and also the determination of the service to be provided, as regards schedule speed, distance between stations and intensity of traffic, are all matters demanding the most careful attention and that they are interdependent. It is evident from the nature of the case, as illustrated by the problems the author has worked out, that the more severe the service and the more intense the traffic, the greater is the superiority of the continuous system. But it is also demonstrated that even for systems of such moderate severity as 22 miles per hour and one stop per 0·88 mile, and even when the intensity of traffic is only one train every 12 to 15 minutes in each direction, the superiority of the continuous system is still very substantial. It is, however, precisely for intense traffic, and for severe services—that is, for services exceeding the limits amenable to steam locomotive methods—that electricity is pre-eminently applicable.

A point of considerable interest, disclosed by a comparison of the values in the penultimate horizontal line in Table IX., is that, with the continuous system, the components of the total cost per train-mile which he has considered are 28 per cent. greater for the 30 miles per hour one stop per 1·32 mile service than for the 22 miles per hour one stop per 0·88 mile service, while with the single-phase system, the cost per train-mile is 37 per cent. greater for the former than for the latter service. This is another point of view from which the greater appropriateness of the continuous system for severe services is apparent.

With the object of basing his comparisons on thoroughly authenticated cases, the author has taken for the continuous-electricity services roads employing pressures of some 600 volts at the trains. There are, however, now a considerable number of roads employing a pressure of 1,200 volts with conspicuous success; indeed, in some of these instances, single-phase equipments have been replaced by 1,200-volt continuous-electricity equipments. As early as 1904 the author urged the advantages of doubling the customary pressure for continuous-electricity traction systems, and based his comparisons on the precise lines which are now being so successfully adopted. Upwards of a dozen roads have now adopted the 1,200-volt continuous-electricity system of traction. This system effects distinct economies over the 600-volt system, and very appreciably accentuates the contrast between the continuous-electricity system and the single-phase system.

THE WOOD PULP AND PAPER MILLS OF THE ANGLO-NEWFOUNDLAND DEVELOPMENT CO.

A LARGE HYDRO-ELECTRIC SCHEME.

(*Concluded from page 643.*)

Generator Turbines.—The turbines in the power house are also of the double type, but, unlike the grinder turbines, have only a single spiral inlet. They each have left and right discharge pipes. The junction inlet pipe rises from the main inlet pipe at an angle of 60 deg., and in this junction pipe is placed the butterfly valve, which is fitted with a hand-operated worm and quadrant for the purpose of shutting off the water. The two curved discharge tubes cross downwards into the draught tubes, which are cut obliquely with a view of securing a more convenient discharge of the tail water. The normal speed of operation of these sets is regulated to 375 revs. per min., which can, by means of the previously described apparatus, be altered as desired between 356 and 394 revs. per min. while the machine is working. It is further guaranteed that a speed variation of not exceeding 12 per cent. will result from a sudden throwing off of the load.

The electric generators, whose constant load capacity is 1,700 kw., supply a three-phase current of 1,800 amperes per phase at 600 volts and a frequency of 50 with a power factor of 0·8, and were built by Messrs. Brown, Boveri & Co., of Baden. Each set has an exciter attached which is constructed for a simultaneous excitation of two dynamos and for a load of 43 kw. at 115 volts. The variation of pressure from full load to no load varies from 8 to 20 per cent. The construction of the generator turbines, as well as the speed regulators, is very much the same as that of the 4,000 H.P. units. Mention may, however, be made of the pressure regulator attached to each generator turbine, the duty of which is to clear an opening for the outrush of water which occurs as a result of the turbine valve being quickly closed. This prevents an undesirable increase of pressure in the pipes. The fundamental idea of this apparatus has already been fully described

Digitized by Google

by Prof. Prasil,* but is carried out in the present instance on a large scale in conjunction with the employment of a servo-motor. The discharge tubes of this pressure regulator empty themselves into the tail water, and are so bent off in their lower section that the violent outrush of escape water cannot attack the canal walls and bed.

The Oil-pump Installation.—Four three-cylinder piston pumps supply the necessary oil pressure for the plant, while for the equalisation of the pressure two air vessels of 2 ft. 4 in. diameter and 9 ft. 4 in. height are installed. The reservoir has an oil capacity of 1,760 gallons, and is installed in such a position that all the used oil from the regulators, including the drip, can flow back by gravity into the reservoir, being cleansed on the way by a filter.

The construction of the pumps exhibits some interesting features, due to their compact design and range of delivery. The pump is completely enclosed, rendering it possible for all

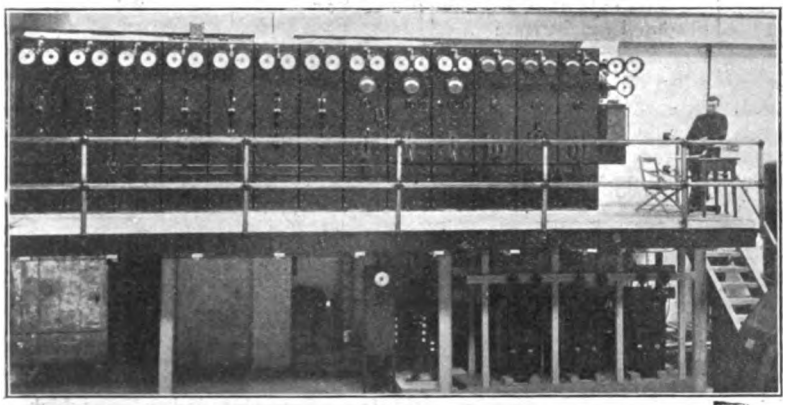

FIG. 7.—VIEW OF THE MAIN SWITCHBOARD WITH TRANSFORMER AND ARC LIGHTING APPARATUS UNDERNEATH.

the moving parts to circulate in an oil bath. The suction valve forms a part of the pump piston itself, whilst the delivery valve is arranged in the cover of the pump cylinder. Both valves work in conjunction with cataracts in such a manner that when a reversal of the stroke occurs the valve disc sinks softly into its seat, thus securing a noiseless working. In the case of the suction valve, which forms the movable cover of the pump piston, this cataract action is produced as follows: The hollow is rigidly enclosed by the pump piston. In the

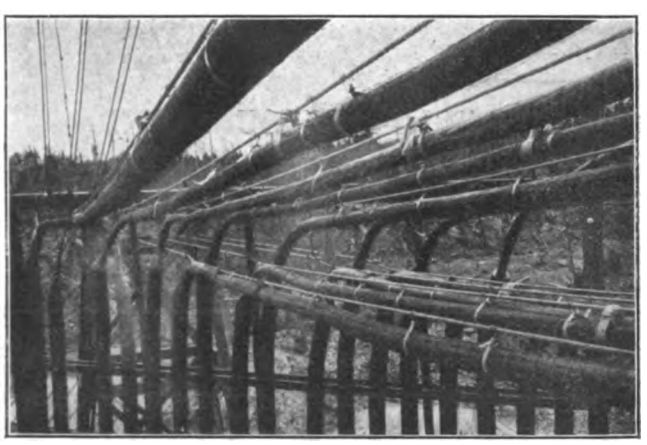

FIG. 9.—METHOD OF SUSPENSION AND ENTRANCE OF CABLES TO CONDUIT.

bore of the rod is a small piston, which can be moved outwards by means of a small hand wheel at the end of the rod, and is thus able to close the openings. A small cataract piston is rigidly connected with the hollow rod, and consequently also with the pump piston. The surrounding casing and the cover

* "Schweizerische Bauzeitung," 1896, "Die Turbinen und deren Regulatoren," Vol. XXVIII., Nos. 20-26.

of the cataract piston, which in its entirety forms the suction valve, is free to slide along the moving rod for a distance corresponding to the permissible valve stroke. Finally, under the pistons passages are arranged, which by means of the hollow rod can communicate with the openings, and in this way bring the chamber over the piston into communication with the chamber under the piston. If now the opening is partially

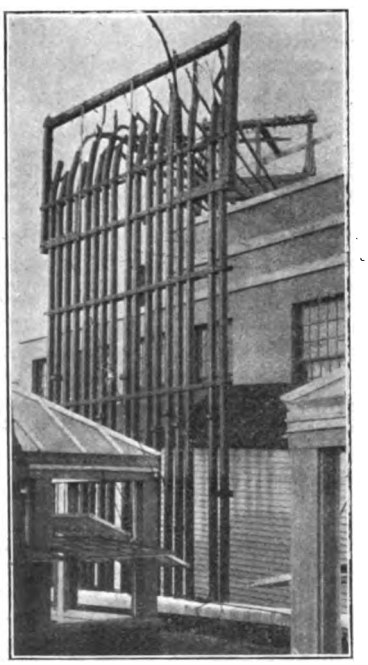

FIG. 8.—CABLES ENTERING POWER HOUSE. The pipes rise 50 ft. above the roof and 65 ft. above the switchboard.

closed through the small piston, the flow of the oil is checked, and on that account the casing can only move slowly relatively to the piston, and the pump piston becomes a rigid whole, and the suction valve, which is identical with the casing, can only, therefore, move slowly in its seat. This cataract action is attained in a somewhat simpler way through the pressure valve. The valve disc is here under the pressure of the helical spring, which can be regulated from the outside, and possesses in its hollow a piston, which extends a few millimetres into the casing

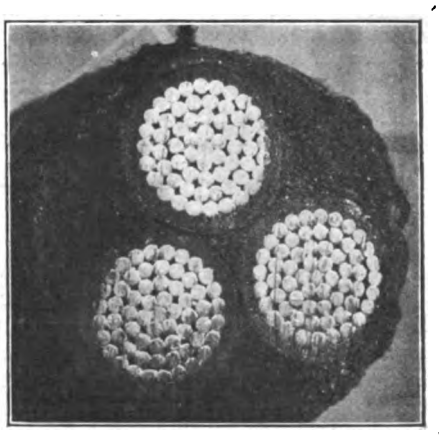

FIG. 10.—AERIAL POWER CABLE USED AT GRAND FALLS. Diameter 4½ in.

of the valve seat. In addition, there are openings in the valve seats, by which the speed of the oil compressed by the piston from the casing during the downward passage of the valve can be regulated, and thus procure the desired gentle movement of the valve disc into its seat.

The number of revolutions of the pump reaches 178 per minute, and the working pressure is 150 lb.; for this 80 gallons

Digitized by Google

of oil per minute can be delivered by a three-cylinder pump. The speed, however, can conveniently reach 200 revs. per min., in which case the delivery increases to 92 gallons per minute.

Each group of pumps is driven by a motor, the speed of which is reduced from 710 to 180 revs. per min. by helical gearing running in oil. Each of the pumps is connected by means of a friction clutch to the shaft of its respective spur gearing, by which means each pump can be switched on and off as desired while working.

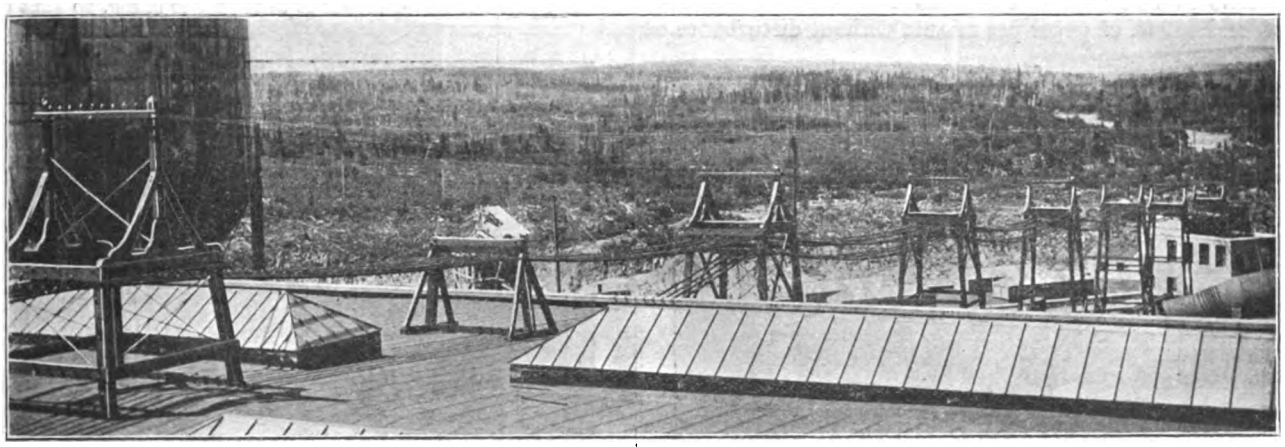

FIG. 11.—VIEW OF THE TRANSMISSION LINE FROM THE MILL ROOF.

Switchgear and Transmission Line.—The switchboard equipment of this plant was supplied by the Westinghouse Electric & Mfg. Co., and was planned and built throughout with an eye to ruggedness and hard service, unadorned with embellishments of any kind. There are (*see* Fig. 7) three exciter panels, three generator and seven feeder panels, each controlling two power circuits to the mill. Each feeder is fitted with a watt-meter on its own panel. All switches are of the positive break, laminated brush, oil type, and are capable of releasing their full rated load without injury. Voltage regulation is effected by means of a Tirrell five-voltage regulator, so that the switchgear is operated under very nearly automatic conditions.

There are 14 power circuits leaving the station, and the problem of getting these out of building and to the mill presented some difficulties. As stated above, the station is in a deep ravine 60 ft. below the yard level, and is surrounded by other buildings, conveyors, &c., thus making the entry of the cables a serious matter. The accompanying photographs (Figs. 8 and 9) give some idea of the solution adopted. During construction 18 6 in. wrought-iron conduits were placed in the concrete wall directly behind the switchboard, and these emerged at each power switch. These pipes rise to a height of 60 ft., at which point the cables are fixed to the messengers, and an overhead line is used. The power cables (Fig. 10) used here are probably the largest of the kind in the world employed for overhead work. Each circuit from the switchboard to the mill consists of three cables arranged in clover leaf form, having $\frac{1}{4}$ in. Para rubber between the conductors, which are taped double and backed up with jute for $\frac{3}{4}$ in. all round and between. Over all is a double heavy braid, which is weather-proofed. The smallest of these cables is 500,000 circular mils and the largest are 800,000 and 1,000,000 circular mils. The 1,000,000 circular mils conductors weigh nearly 20 lb. to the foot, so that special construction was necessary to provide adequate support. The cables are carried to the mill on Siemens-Martin double-galvanised $\frac{1}{2}$ in. seven-strand wire, and hung to it by Boston and Marlin cable clips, alternating each 4 ft. of conductor. The whole line is supported every 80 ft. on Georgia pine towers 40 ft. high and 8 ft. square at the top. The towers are also utilised for carrying watch clock, fire alarm, telephone and signal lines, as well as service and water supply pipes to the mill. The ruggedness of the transmission line is fairly shown in the photos (Figs. 11, 12 and 13).

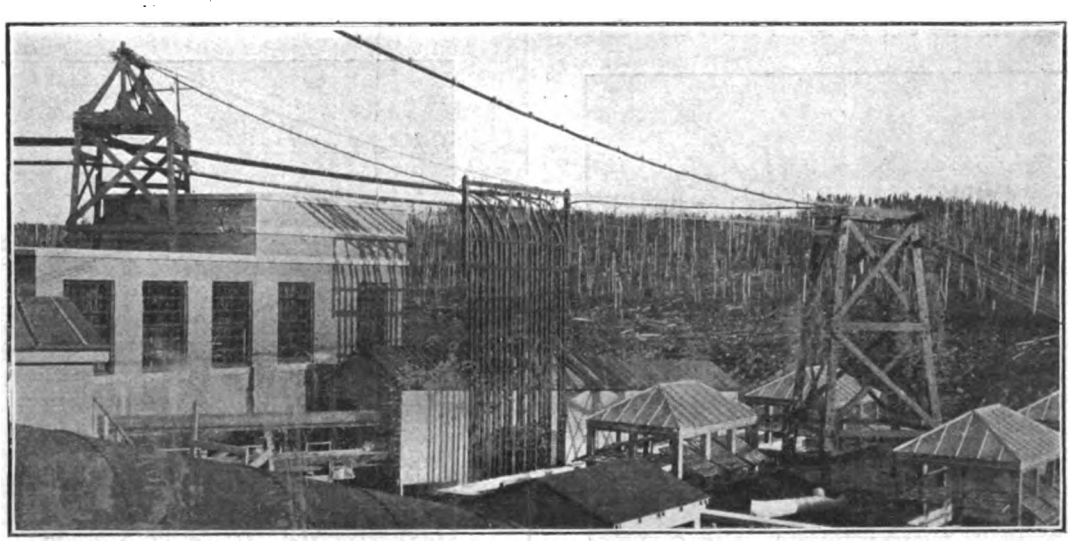

FIG. 12.—EXIT OF CABLES FROM POWER STATION.

All the machinery in the mill is driven electrically. There are at present a number of three-phase induction motors supplied by the Westinghouse Electric & Mfg. Co., with an aggregate output of 7,000 H.P., and varying from $2\frac{1}{2}$ H.P. to 300 H.P. in capacity. The motors have been placed in their positions with great care and attention to the nature of work to be done, with the result that in this mill, after nearly nine months of continuous 168 hours a week operation, with only a few minute occasional shutdowns, not a single fault has developed in any motor, a state of things which speaks very highly for

Digitized by Google

the architect who decided on their positions and the manufacturers who supplied them. There are at present 130 motors in the mills. Two types of motors are used, squirrel cage and collector ring, employed according to adaptability and load, and the power factor of station under normal operation averages from 80 to 85 per cent.

The largest motors in the plant are of the 300 H.P. variable-speed type. They are used to drive the paper machines. With these motors a uniform change of speed in paper manufacture is possible in increments of 5 ft. to 6 ft. between limits of 325 ft. and 590 ft. of paper per minute without disturbance of

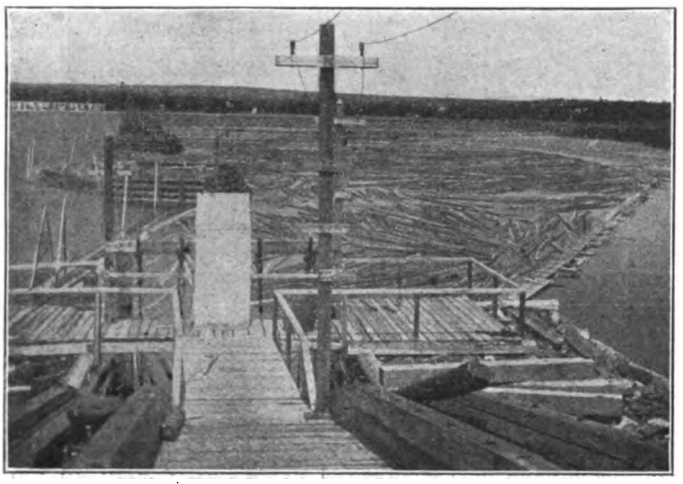

FIG. 13.—VIEW OF MAIN LOG POND.

any kind under continuous operation. There has been much discussion and study on this subject of paper machine drive and its merits and possibilities, but its flexibility and reliability alone are a clinching argument in its favour. The controller for these machines is placed close to the machine tender's hand for operation when necessary. There is no running up and down stairs looking for trouble; no attendance is necessary. There are no steam engine troubles, and no anxiety as to whether the speed is or is not changing, for with the system used the machine tenders can be at all times sure that the

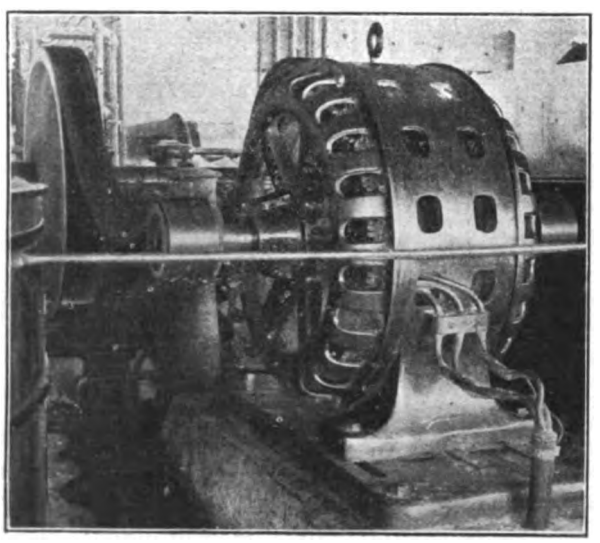

FIG. 14.—100 H.P. MOTOR DRIVING BEATING ENGINE.

driving engine is constant in speed. That machine which is auxiliary to the forming and drying of the paper, such as pumps, winders, &c., is driven by separate constant-speed motors. Figs. 14 to 16 show examples of the motors used.

Fig. 18 shows the wood conveyor working between the pond and wood-preparing room. This conveyor is 1,900 ft. long, and can be stopped or started by workmen at intervals of 40 ft. along its entire length by means of push buttons,

The mill lighting is done locally by incandescent lamps, while the general lighting is effected by Cooper-Hewitt vapour lamps of the alternating-current automatic type. The vapour lamps make an ideal lamp for paper mill-lighting, as their large volume, intense and steady glow provide just the qualities desired. All lamps are placed above the travelling crane, which traverses the entire length of the machine room. The question of colour effect has been of no importance thus far, for in the small amount of coloured paper made it is found that effect upon the same colour is always the same, so that opera-

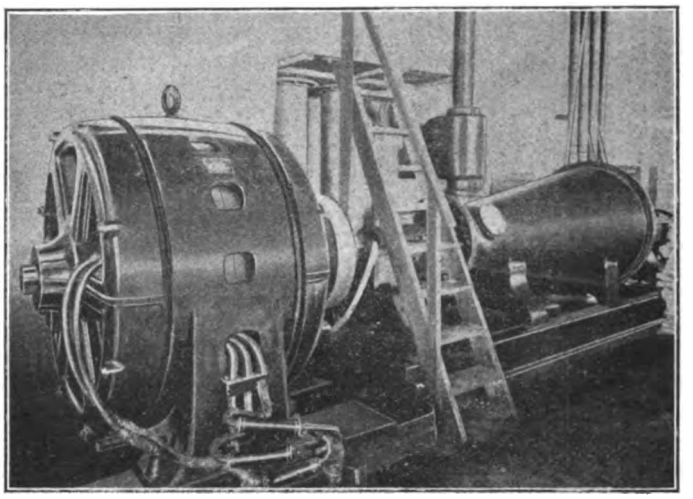

FIG. 15.—100 H.P. MOTOR DRIVING JORDAN ENGINE.

tors soon become entirely accustomed to it, and the materials effect the senses as in daylight.

Distribution is effected on the block system. Each room has a power and lighting centre from which all power cables are taken to the individual motors under the concrete floor; in this way all the walls and ceiling are kept clear of the electric wiring, except where absolutely necessary.

The lighting current is taken from the power 'bus bars in the station. It is transmitted on the three-phase system, and is

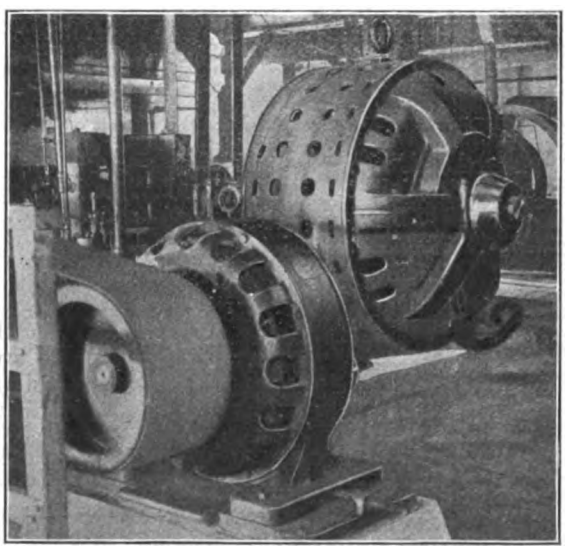

FIG. 16.—30 H.P. MOTOR DRIVING WINDER, AND 300 H.P. DIRECT-CONNECTED VARIABLE SPEED MOTOR DRIVING PAPER MACHINE.

distributed single phase to static transformers placed about the various apartments. A lighting centre is shown in Fig. 17. A lighting voltage of either 220 or 110, as desired, is used. A superstructure placed over the transmission line carries lighting wires to both mill and town. Electric heating is used to a large extent wherever the steam installation is distant or expensive to instal. Automatic signals are a feature in this mill, and play an important part in all departments of manufacture.

Digitized by Google

The power and lighting system is an earthed conduit one throughout, while the town lighting and heating system is not an unimportant item in the electric installation at Grand Falls.

In the generating station under the switchboard are three Westinghouse 50 kw. lighting transformers, stepping up the current from 600 to 2,200 volts for the town houses and street lighting. Single-phase distribution is used entirely, and local transformers reduce the pressure to 440, 220 or 110 volts as desired for power or lighting.

There are at present over 300 buildings lighted, which number will soon be increased to 400. All these are lighted entirely by incandescent lamps. Outhouses, barns, &c., are also so lighted, so that there is absolutely no use or need for kerosene oil in any part of the town for lighting or heating. The streets are lighted by 25 series of enclosed arc lamps, with the usual regulator at the station, and were furnished by the Westinghouse Electric & Mfg. Co. Single-phase motors are used throughout the town for portable wood-sawing apparatus, wood-working shops, well pumping, the voltage being 220.

The citizens and workmen of Grand Falls have been wonderfully keen in appreciating the opportunities open to them by the cheap supply of electricity available, and irons, ovens, cookers and other heating apparatus are being ordered, for they are discovering that at the nominal rates charged for heating and cooking utensils, electricity is cheaper than wood

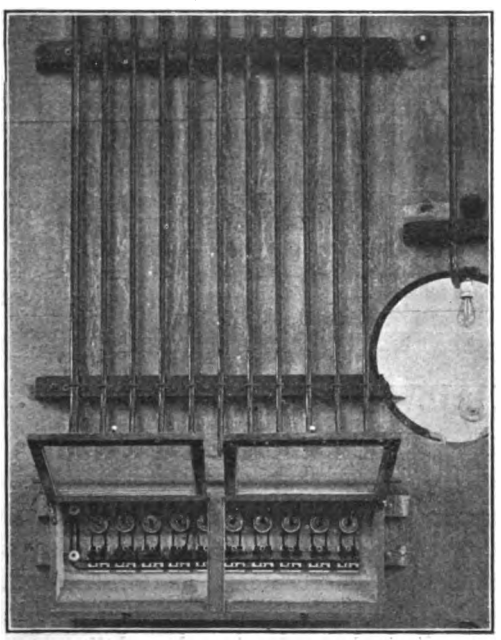

Fig. 17.—Typical Lighting Centre.

and coal during the warm months of the year. It is confidently expected that within two years 50 per cent. of the cooking in the town will be done by electricity.

A regularly appointed crew of firemen are assisted in their duties by an automatic electric fire alarm. At each street junction are placed fully equipped hose houses and hydrants, and at intervals half-way between street junctions are fire ladders, which are hung on racks well protected from the weather. Fire cards are posted in each house giving the position of the alarm stations and how to handle them. In this connection it may be mentioned that the alarm box is handled by the same type of switches as is installed for house lighting, so no possible confusion or mistake is possible in working it, even by the children.

The company have provided communication facilities among its officials, employés and departments by installing a central telephone station in the main office. This system comprises nearly 300 miles of telephone wire, including 12 local lines and three trunk lines. All the wood departments, some of them 150 miles away, are brought into direct communication at any minute, and the same is possible with the town of Botwood, on the sea shore, 25 miles distant. The whole system has been planned and carried out with the idea of permanency, flexibility, resistance to high winds and variable weather, economic upkeep within reasonable limits without stint, and ability to expand if future expansion of the general scheme requires it. Considering the size of the town, its age and population, there is hardly room for doubt that Grand Falls, Newfoundland, as regards the application of electricity to commercial and domestic requirements, holds a very high position among the cities of the world. The inhabitants have made it from choice one of the vital necessities, not only of their daily occupation, while in their own homes it has become essential to their mode of living.

The thoroughness with which the Anglo-Newfoundland Development Co. have dealt with their electrical equipment is only characteristic of its attitude in all other branches and departments of the gigantic enterprise which has transformed a wilderness into a live and a living industry and its attending city. That the end foreseen at its inception has been accomplished is amply shown by the grand success attained since the initial commencement of operations, and which has persisted during all the months that have followed, during which all previous records in starting up and in producing have been broken. Nor is this state of things confined to the mill, for it is significant of the satisfaction and contentment on the part of a people that they evince such a general desire of remaining to settle down in Grand Falls. In fact, the houses are snapped up and furnished as fast as 500 men can build and complete them.

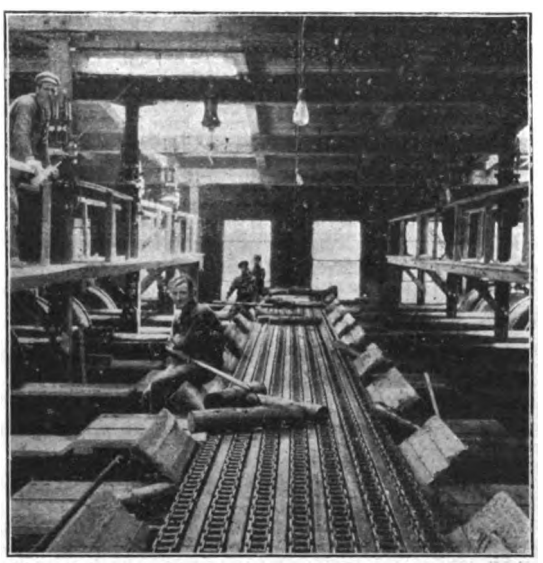

Fig. 18.—Motor-driven Log Conveyor entering Barking and Cleaning House.

The whole plant, consisting of complete turbines and regulators, was delivered in the spring of 1909, commenced working in the autumn of the same year, and has continued without interruption since. According to the results obtained, the guarantees of the wear of the turbines and speed variations under changing loads have been more than reached.

The contract for the turbine machinery was, after competition, awarded to the German firm of Amme, Giescke & Konegen Co., of Brunswick.

To the enterprise and farsightedness of Lord Northcliffe, whose place in the newspaper world of his time is unique, is due the inception and completion of an industrial departure of the first magnitude, and one which may have a great influence on the art and craft of paper making in the coming time.

In concluding this description of the new paper mill in Newfoundland we have to thank the proprietors of this interesting plant for providing us with the details and illustrations given above. It is manifest that great credit is due to Mr. Mayson M. Beeton and to Mr. G. F. Hardy, who prepared the plans and under whose direction the works were constructed and equipped. We are also indebted to Mr. T. F. Judge, who supplied us with details of the switchboard, transmission lines and power work generally.

The Rates for Subscription to "THE ELECTRICIAN" are as under

	YEAR.	HALF-YEAR.	QUARTER.	
United Kingdom .	26s. 0d.	13s. 6d.	7s. 0d.	Post free,
Canada	28s. 3d.	14s. 6d.	7s. 6d.	payable
Postal Union ...	30s. 0d.	16s. 0d.	8s. 0d.	in advance.

New volumes of "THE ELECTRICIAN" commence in April and October.

(This charge includes all Supplements.)

Vols. I. to LXIV. can now be supplied. Price on application.

"THE ELECTRICIAN" SERIES OF STANDARD ELECTRICAL BOOKS

can be obtained of all Booksellers at Home, in the Colonies, and Abroad.

THE "ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. Published annually in February, corrected to mid-February. Established 1882. A very valuable advertising medium, covering the entire Industry. SUBSCRIPTION Price (which is received *in advance* up to Dec. 31st in each year for the next following edition) 8s. 6d. nett, postage 9d. extra. Published price 15s. nett, postage 9d. extra. Postage to British Colonies, 2s.; Europe, 2s.; U.S.A., 3s. 6d.; other countries, 2s. 6d. *Digest of Contents sent free on application.*

THE "G.T." GEOGRAPHICAL DIRECTORY OF THE U.K. (Electrical Section). Subscription 5s., post free.

"THE ELECTRICIAN" PRIMERS (81 Primers in all, and a GLOSSARY). Single Primers 3d. each post free. *New and Enlarged Edition in One Complete Vol. or Three separate Vols. now ready.* FULL PROSPECTUS FREE.

ELECTRIC TRACTION ON RAILWAYS. By Philip Dawson. Price 25s. nett. *Prospectus free.*

ALTERNATING-CURRENT MOTORS. By Dr. Rudolf Goldschmidt. Price 6s. 6d.

THE SHOT-FIRER'S GUIDE: A Practical Manual on Blasting and the Prevention of Blasting Accidents in Mines, Quarries, &c. By W. Maurice. Price 3s. 6d. nett.

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. Wilkinson, M.I.E.E. *New Edition.* Now ready. Price 15s. nett.

ELECTRIC BLASTING APPARATUS AND EXPLOSIVES: With Special Reference to Colliery Practice. By W. Maurice. Price 8s. 6d. nett.

THE ELECTRIC FURNACE IN IRON AND STEEL PRODUCTION. By John B. C. Kershaw, F.I.C. Price 3s. 6d. nett.

BRAKES FOR TRAMWAY CARS. By H. M. Sayers. Price 3s. 6d. nett.

THE MECHANICAL DESIGN AND CONSTRUCTION OF COMMUTATORS. By R. Livingstone. Price 6s. nett.

THE ALTERNATE-CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Prof. J. A. Fleming, M.A., D.Sc., F.R.S. [abroad 13s.

VOL. I.—Price 12s. 6d. post free, abroad 13s. VOL. II.—Price 12s. 6d. post free,

HANDBOOK OF THE ELECTRICAL LABORATORY AND TESTING ROOM. Very fully illustrated. By Dr. J. A. Fleming. Vol. I., 12s. 6d. nett, Vol. II., 14s. nett.

ELECTRIC LAMPS AND ELECTRIC LIGHTING. By Prof. J. A. Fleming. 6s. nett.

ELECTRICAL LABORATORY NOTES AND FORMS. Arranged by Dr. J. A. Fleming, M.A., F.R.S. Single copies 4d. nett, or in dozens at 3s. 6d. nett. Complete Sets of 50 Notes and Forms, 12s. 6d. nett, or in strong portfolio, 14s. nett; or bound in strong cloth, 15s. nett. Spare Copies of Tabular Sheets, 1s. per dozen. Portfolios, 1s. 6d. each. Sectional paper, 1s. per dozen sheets. *Complete Prospectus post free on request.*

A SMALLER SET of only 40 Forms, bound strong cloth. Price 7s. 6d. nett.

CENTENARY OF THE ELECTRIC CURRENT—1799–1899. By Prof. J. A. Fleming, F.R.S. Price 1s.; strong cloth 2s. 6d.

ELECTRICITY METERS: THEIR CONSTRUCTION AND MANAGEMENT. By C. H. W. Gerhardi. Profusely illustrated. Price 9s. nett.

ELECTRICITY IN HORTICULTURE. By Prof. S. Lemstrom. Illustrated. 3s. 6d. nett.

RADIO-ACTIVITY: AN ELEMENTARY TREATISE, FROM THE STANDPOINT OF THE DISINTEGRATION THEORY. By Fredk. Soddy, M.A. Fully illustrated. Price 6s. 6d. nett.

ELECTROMAGNETIC THEORY. By Oliver Heaviside. Vol. I. Price 12s. 6d. Vol. II. Price 12s. 6d. *Vol. III. in the press.*

MOTIVE POWER AND GEARING FOR ELECTRICAL MACHINERY. By E. Tremlett Carter, C.E., M.I.E.E. Revised by G. Thomas-Davies, A.M.I.E.E., F.C.S. Price 12s. 6d. nett.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. Ewing, B.Sc., F.R.S., F.R.S.E. Price 10s. 6d.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. Kennelly and H. D. Wilkinson, M.I.E.E. Price 6s. 6d.

ELECTRIC MOTIVE POWER. By Albion T. Snell. Price 10s. 6d. nett.

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. Gelpel and H. M. Kilgour. Price 7s. 6d. nett.

ELECTRICAL TESTING FOR TELEGRAPH ENGINEERS. By J. Elton Young. Price 10s. 6d.

STUDENTS' GUIDE TO SUBMARINE CABLE TESTING. By H. K. C. Fisher and J. C. H. Darby. Price 7s. 6d. nett.

SIGNALLING ACROSS SPACE WITHOUT WIRES: THE WORK OF HERTZ AND HIS SUCCESSORS. With new Chapter on Tuning. By Dr. Sir Oliver J. Lodge. Price 5s. nett.

THE ART OF ELECTROLYTIC SEPARATION OF METALS. By Dr. G. Gore, LL.D., F.R.S. Price 10s. 6d.

ELECTRO-CHEMISTRY. By Dr. George Gore. Price 2s.

BEGINNER'S MANUAL OF SUBMARINE CABLE TESTING AND WORKING. By G. M. Baines. Price 7s. 6d. nett.

CARBON MAKING FOR ALL ELECTRICAL PURPOSES. By Francis Jehl. Price 10s. 6d.

"THE ELECTRICIAN" WIREMAN'S POCKET BOOK. Edited by F. C. Raphael. Price 5s. nett.

"THE ELECTRICIAN" HANDY WIRE TABLES FOR THE POCKET. By P. B. Down, Wh.Ex., A.M.I.Mech.E. Price 2s. 6d. nett.

THE RATING OF ELECTRIC LIGHTING, ELECTRIC TRAMWAY, AND SIMILAR UNDERTAKINGS. By W. G. Bond, M.I.E.E. Price 2s. 6d. nett.

DRUM ARMATURE WINDING AND COMMUTATORS. By F. M. Weymouth. 7s. 6d.

PRIMARY BATTERIES: THEIR CONSTRUCTION AND MANUFACTURE. By W. R. Cooper. Price 10s. 6d. nett.

SECONDARY BATTERIES: THEIR CONSTRUCTION AND MANUFACTURE. By E. J. Wade. Price 10s. 6d. nett.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. Price 1s. 6d.

THE LOCALISATION OF FAULTS IN ELECTRIC LIGHT CABLES. By F. C. Raphael. 7s. 6d.

THE STEAM-ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. Beaumont, M.I.C.E., M.I.M.E., &c. Price 6s. nett.

THE ELECTRIC ARC. By Mrs. Ayrton, M.I.E.E. Price 12s. 6d.

TRAMWAY TRACTIVE EFFORT AND POWER DIAGRAM. By Arnold G. Hansard, B.A., A.M.I.E.E. Price 4s. 6d. nett; in Tube, 5s.

THE BRITISH POST OFFICE TELEPHONE SERVICE. Fully illustrated.. Price 3s. 6d. nett.

INTERNATIONAL TELEGRAPH CONVENTION AND SERVICE REGULATIONS. Price 6s. nett. (LISBON REVISION, 1908.)

BOILER FEED WATER. By F. W. Anderson. Price 6s. nett.

(PRELIMINARY) WIRELESS TELEGRAPH CONFERENCE (BERLIN, 1903), PROCEEDINGS AT. Price 8s. 6d. nett.

INTERNATIONAL WIRELESS TELEGRAPH CONVENTION AND SERVICE REGULATIONS (BERLIN, 1906). With complete report of Proceedings. Price 21s. nett.

THE CLASSIFICATION OF ALTERNATE-CURRENT MOTORS. By V. A. A. Fynn, M.I.E.E. Price 3s. nett.

ELECTRIC CRANES AND HOISTS. By H. H. Broughton. *In Preparation.*

PRACTICAL TELEPHONY. By W. Aitken, M.I.E.E. *In Preparation.*

ELECTRIC MAINS AND DISTRIBUTING SYSTEMS. By J. R. Dick, B.Sc., and F. Fernie, A.M.Inst.C.E. *In Preparation.*

THE PRACTICAL WIRELESS SLIDE RULE. By Dr. H. R. Belcher-Hickman. Price 2s. 6d. nett. *Nearly Ready.*

THE MECHANICAL DESIGN AND CONSTRUCTION OF GENERATORS. By R. Livingstone. *In Preparation.*

LIGHT, RADIATION AND ILLUMINATION. From the German of Paul Högner, by Justus Eck. *In Preparation.*

The Electrician.

The Oldest Electrical Journal (established as a weekly Journal, 1861-1878).

"THE ELECTRICIAN" INDUSTRIAL SUPPLEMENT.

With "THE ELECTRICIAN" for Sept. 14, 1906, was issued the first of a series of "Industrial Supplements," to be published from time to time with "THE ELECTRICIAN." The fifty-first issue of the Supplement was published (Gratis) with the number of "THE ELECTRICIAN" for July 22.

The "INDUSTRIAL SUPPLEMENT" is a comprehensive record of developments in Electrical Plant, Machinery, Apparatus, Accessories, Sundries and Materials, and of their proved suitability for various Industrial purposes.

SPECIAL NOTICE.

NOW READY.—Vol. LXIV. of "THE ELECTRICIAN" (1,085 pages) bound in strong cloth. Price 17s. 6d.; post free, 18s. 6d. Now ready. Cases for Binding. Price 2s.; post free, 2s. 3d.

A complete set of "THE ELECTRICIAN" can be supplied. A number of odd volumes and some odd old back numbers, to help in making up complete sets, are also available.

RAILWAY ELECTRIFICATION.

What is sometimes referred to as "the battle of the gauges" is well known to those who followed the development of the steam railway. At first each railway considered its own interest rather than the interests of railways as a whole; but as networks extended it became clear that interchange of traffic was desirable, and any serious differences in equipment became limited to the broad and narrow gauges, though later on brake equipment introduced difficulties once more. It was a long time, however, before the narrow standard gauge won the day, and it is not so very many years ago that the Great Western Railway presented the curious feature of a line with two gauges. Very possibly, with a desire for more powerful locomotives, some engineers may still wish that the broad gauge were available, though, on the whole, it is probably a good thing that the narrow gauge emerged victorious.

The same sort of difficulty is now becoming evident in the electrical equipment of railways. Electrical working is becoming more extended. Conversion to this form of locomotion is not taking place as quickly as one might desire, but, nevertheless, substantial progress is being made. So long as suburban traffic alone is in question, the point is not very urgent, but with the electrification of portions of main lines the interchange of traffic will become a more important matter. From this point of view a plea was put forward by Mr. GEORGE WESTINGHOUSE last week in a Paper read

Digitized by Google

at the joint meeting of the Institution of Mechanical Engineers and the American Society of Mechanical Engineers. Mr. WESTINGHOUSE urged that a choice should be made once for all between the continuous-current, single-phase and three-phase systems.

We quite admit that it would be an advantage to have one system, and one only, as Mr. WESTINGHOUSE points out. In that case the attention of engineers would be concentrated upon the perfection of a single system, doubtless with correspondingly satisfactory results. Also railway directors would feel that electrical engineers were working with a united front, and they would no longer be confused by a choice of systems. The fact that the benefits of electric traction can be obtained by at least three different systems, and that electrical engineers differ materially in the opinions they express, has, no doubt, had a retarding effect.

We fear, however, that the advice of Mr. WESTINGHOUSE is a counsel of perfection, and is almost impracticable. The choice is no simple one. It is not merely a question of deciding a single point of difference, such as the broad and narrow gauges, but a choice between systems whose respective virtues depend upon the conditions to be met. Moreover, would there not be some risk in making a final choice at this comparatively early period in the existence of railway electrification? Suppose, for example, that such a proposition had been made some years ago, the choice would then have been between continuous current and three-phase. Since that time, however, and it is less than 10 years ago—the position of affairs has quite altered. The single-phase system has sprung into existence, and has shown itself capable in a very short time of proving a serious rival to the older systems. It does not follow, of course, that within the next 10 years any similar advance will be made, but it appears to us that it would be extremely dangerous to exclude the possibility of advance along any direction at this early date.

Further, if the railways all belonged to the State it would be a simple matter to consider them as a whole, and possibly to choose that system which appeared best to meet the requirements of the railways generally. At present we are not in this position. Thus, as pointed out by Mr. J. G. WILSON in the discussion, we have the requirements of the Great Eastern Railway and of the Great Northern Railway, although near neighbours in London, very materially different. The Great Eastern Railway has a very heavy suburban traffic, whereas the Great Northern Railway is much more limited to main line working. It cannot be expected, therefore, that one railway would sacrifice economical working for the sake of another.

Apart from this large question, there was discussed at the meeting to which we have just referred the relative merits of continuous-current and single-phase systems for railway working. Such a programme is almost a *sine qui non* at the present time where electric railway problems are discussed broadly. As time goes on, however, it becomes increasingly evident that such discussions are futile. Generally, figures and hypotheses on which to base an argument for one system or another are of very little use, for, as pointed out very clearly by Mr. C. F. SCOTT, comparatively small differences in the assumptions made are liable to make considerable differences in the conclusions reached. As a matter of fact, all that we can say is that actual results of working are the only results that are of any value. We do not suggest that either system is capable of universal application to the exclusion of the other, but nevertheless, if it be found that the Midland Railway and the London, Brighton & South Coast Railway obtain satisfactory results from single-phase working, by which we mean satisfactory results commercially as well as electrically, then the single-phase system cannot be considered out of court, even for suburban traffic. In terms of the historic phrase, it is better to "wait and see," for the results of actual working are those on which the systems must finally rise or fall.

OBITUARY.

GEORGE FLETT.

As briefly recorded in our last week's issue, the death of Mr. George Flett took place on Wednesday, July 27th, at Birmingham, as the result of a motor car accident.

George Flett was born in January, 1855, at Wick, and had thus only reached the comparatively young age of 55 when he met with his untimely accident. He received his early education in Glasgow—a town which has played a great part in the supply of engineers—and as long as 28 years ago became associated with Messrs. Dick, Kerr & Co. As is of course well-known to our readers, there is perhaps no British firm which has played so large a part in electric tramway development in this country as have Messrs. Dick, Kerr; and with this pioneer work Mr. Flett was intimately connected. He saw the gradual extinction of the horse tramways, the partial adoption of cable traction, and the general use of electric traction. In our Editorial Notes a week or two ago we drew attention to the enterprise of the London County Council in spreading a network of electrically worked tramway routes over north and south London, but it must not be forgotten that the realisation of this excellent idea would not have been possible without the engineering and contracting experience of certain firms, of which Mr. Flett was not an unworthy representative.

While Mr. Flett's early experience was chiefly gained in contracting, for the last 12 or 13 years he had been closely associated with the manufacturing side of electrical engineering. In this work he had played a not unimportant part in some very notable developments. Among these may be mentioned the electrification of the Liverpool and Southport section of the Lancashire & Yorkshire Railway, while contracts for electric tramways at home and abroad were constantly engaging his attention. In connection with the Liverpool and Southport electrification it may be mentioned that this was again pioneer work, and that, as shown in the Papers read the other day before the Institution of Mechanical Engineers, the results there obtained have not been without their effect on the future development of electric traction.

Having made during his career prolonged journeys abroad, it was natural that he should have become associated with electrical schemes in other countries than his own. At different periods, in fact, he succeeded in carrying through important electrical contracts in Japan and the Far East. In addition to being managing director of Messrs. Dick, Kerr & Co., Mr. Flett was also a director of the Metropolitan Amalgamated Railway Carriage & Wagon Co., the Patent Shaft & Axletree Co., the Projectile Co., the British Aluminium Co., the Rio de Janeiro Tramway, Light & Power Co., the Mexican Light & Power Co., Monterey Railway, Light & Power Co., and the British Engineering Co. of Egypt.

LEEDS CORPORATION ELECTRICITY SUPPLY ACCOUNTS.

Although the records of the Leeds Corporation electricity department for the past year show that electricity is being employed to an increasing extent both for lighting and power, the revenue obtained is much less than that recorded a year ago, notwithstanding that a greater number of units have been sold. This is accounted for by the reduction in consumers' accounts owing to the replacement of carbon lamps by metal filament lamps, and by the fact that a greater proportion of the units sold has been for power and heating.

The unusual conditions prevailing during the year may be gathered from the fact that, in spite of an increase of 394 in the number of lighting consumers, bringing the total number of such consumers to 6,026, the sales of energy for private lighting decreased from 5,241,523 units in the year ended March 31, 1909, to 4,575,975 for the 12 months terminated on March 31 last, *i.e.*, a decrease of no less than 12·7 per cent. The consumption of energy for public lighting has also been reduced owing to the adoption of more economical lamps, notwithstanding a slightly extended use of electric lighting.

On the other hand, it is very gratifying to record a substantial increase in the sales of energy for power and heating. This increase is not proportional to the growth in the aggregate horse-power of the motors connected to the mains, probably largely due to the continued depression in the trades in which electric power is most largely used. It is worth noting, however, that the total horse-power of motors connected during the 12 months is greater than in any previous year, so that under normal conditions a great expansion of supply will be expected. On March 31 last 2,088 motors were in use, of a total capacity of 12,836 H.P., an increase of 378 motors and 2,894 H.P. in the year. The number of consumers for power and heating was on the same date 1,127, so that, including the 6,026 lighting connections, there are 7,153 consumers connected to the supply mains.

In the following table, the consumption of energy is allocated to the different classes of supply.

—	No. of units, 1910.	No. of units, 1909.	Revenue, 1910.	Revenue, 1909.
Private lighting	4,575,957	5,241,523	£64,518	£73,087
Street lighting	937,193	988,785	4,881	5,150
Power and heating	6,908,014	6,164,810	29,669	25,911
Total	12,421,164	12,395,118	£99,081*	£104,148

A consideration of the revenue, &c., obtained per lamp and horse-power installed will prove instructive at this juncture. The figures for the last two years are as follows :—

—	Year ended March 31, 1910.	Year ended March 31, 1909.
Lighting.		
Units sold per 35 watt lamp installed	17·73	19·69
Average net price per unit	3·02d.	3·01d.
Revenue per lamp installed	4s. 5·58d.	4s. 11·34d.
Power and heating.		
Units sold per H.P. installed.....	595	686
Average net price per unit.....	1·03d.	1·01d.
Revenue per H.P. installed.....	£2. 11s. 1d.	£2. 17s. 8d.
Total sales.		
Units sold per 35 watt lamp (or equivalent) installed	20·66	22·91
Average net price per unit	1·91d.	2·02d.
Revenue per 35 watt lamp (or equivalent) installed	3s. 3·55d.	3s. 10·20d.

It will be noticed that there is a considerable reduction in the number of units used per horse-power of motors installed. This figure, of course, is to some extent an index of the state of the industries concerned during the periods in question, and there is little doubt that the revival of trade will result in the power supply side of the undertaking largely overshadowing the sales for lighting.

* Includes £13 for sundries.

The maximum load upon the plant during the past winter was 8,900 kw., compared with 8,220 kw. in the previous year, and the load factor works out at 15·9 per cent., the capacity of the generating plant remaining unchanged at 15,740 kw.

Turning now to the cost of generation, it is noteworthy that every group of items, with the exception of rates and taxes, shows a decrease compared with the previous year's figures, the aggregate reduction amounting to no less than £5,763, or more than sufficient to counteract the decrease in revenue.

The undertaking has benefited by a reduction in the price of coal, and in the amount used per unit. The cost of repairs and maintenance has been greatly diminished without any falling off in the attention devoted to the upkeep of the plant; whilst the necessity for extraordinary replacement of plant has for the present practically disappeared, in accordance with expectations previously held out. There has also been a saving in interest, due to the repayment by the Finance Committee of loans at a high rate.

The net result is an increase in the profit for the year, this being £8,930, compared with £8,248 for the year 1908-9. This surplus is the largest recorded in the history of the undertaking, and has been utilised in relief of the consolidated rate, bringing the total sum contributed for this purpose by the undertaking to £54,797.

We give below an analysis of the expenditure during the year ended March 31 last, together with the cost per unit sold, the latter figure being also tabulated for the previous year for the sake of comparison.

		Cost per unit sold. 1909-10.	1908-9.
Generating Costs.			
Fuel	£8,936	0·17d.	0·21d.
Oil, waste, stores, &c.	371	0·01d.	0·02d.
Salaries and wages at station ...	3,874	0·08d.	0·08d.
Repairs and maintenance	1,786	0·03d.	0·05d.
Total Generating Costs	£14,967	0·29d.	0·36d.
Distribution Costs.			
Wages	£2,189	0·04d	0·04d
Repairs and maintenance of mains, fuses, &c.	1,567	0·03d	0·05d.
Stores and miscellaneous.....	400	0·01d.	0·01d.
Total Distribution Costs	£4,156	0·08d.	0·10d.
Management Costs, &c.			
Salaries	£5,223	0·10d.	0·11d.
Printing, stationery, &c.	226	0·00d.	0·00d.
Insurance	369	0·01d.	0·02d.
Miscellaneous	1,156	0·02d.	
Extraordinary renewals	49	0·00d.	0·04d.
Total Management Costs, &c.	£7,023	0·13d.	0·17d.
Rates and taxes	£4,469	0·09d.	0·08d.
TOTAL COSTS (*ex.* capital charges)	**£30,615**	**0·59d.**	**0·71d.**
Capital Charges.			
Interest	£28,031	0·54d.	0·55d.
Sinking fund	31,206	0·60d.	0·59d.
Wages of permanent men not chargeable to loans	299	0·01d.	0·01d.
Total Capital Charges	£59,536	1·15d.	1·15d.
TOTAL COSTS (including capital charges)	**£90,151**	**1·74d.**	**1·86d.**
TOTAL RECEIPTS from all sources	**£99,081**	**1·91d.**	**2·02d.**
Surplus	£8,930	0·17d.	0·16d.

As mentioned above, the whole of this surplus has been handed over to the relief of the rates.

The total capital expenditure on March 31 last was £985,948, or £62. 12s. 10d. per kilowatt of plant installed, and this is apportioned between the various portions of the undertaking as follows :—

		Per cent. of total.
Generating station	£409,391	41·5
Mains, transformers, meters, &c.	526,939	53·5
Cost of provisional order, discount on issue of stock, &c.	49,618	5·0
	£985,948	100·0

The total amount set aside for repayment of debt is £231,707, whilst the reserve fund amounts to £3,150, and a sum of £1,826 has been contributed to capital account from revenue, so that the net amount of debt outstanding is £749,265.

DR. SCHÖNHERR'S PROCESS FOR PRODUCING ATMOSPHERIC NITRATES.

Dr. Schönherr's method for forming nitrogenous products by the electric arc is to be used shortly on a large scale in Norway, and the furnaces which are being erected there will use part of the energy supplied by the large hydraulic plant of Rjukan. In view of the approaching industrial application of the process on a large scale, we give the following brief description of it, from data which have been furnished us by the Badische Anilin & Soda-Fabrik. This firm first operated the process in Germany, and will carry on the work in Norway.

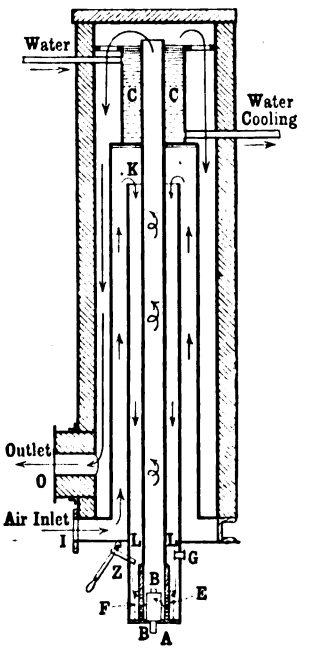
In the course of his researches on obtaining nitrates from the air, Dr. Schönherr found a simpler device than the electromagnetic arc with which we are familiar. It was thought that the arc should burn either intermittently or at least with very rapid vibrations in the air under treatment, such as is the case in the Birkeland-Eyde process. The inventor found that this is not essential, and he therefore uses a steady arc fed by a heavy current, burning very quietly. To carry out this method the arc is made to burn under special conditions. Dr. Schönherr finds that it is impossible to send large quantities of air through a voltaic arc, as is described in many patents, and only a small part of the air actually comes in contact with the arc, so that the resulting gas is very poor. Good results can be obtained by sending air along an arc, but even slow currents of air, and much more so the rapid rush of air which is needed, extinguish the arc, especially an alternating arc, which is the only one to be considered. The inventor succeeds, however, in overcoming all the difficulties inherent in the alternating arc. His principle is that when we send air along an arc not in a straight line, but in a helical or screw-thread path around the arc, the arc then burns steadily. We can thus place the arc inside a rather small metal tube, and it has no tendency to touch the sides. Using only an ordinary straight movement of the air along the arc, the latter would tend to touch the inside of the tube prematurely, so that a metal tube could hardly be used for enclosure purposes, while non-conducting tubes have certain disadvantages. For these reasons industrial practice shows that we must use exclusively arcs burning in the centre of a whirling current of air. The apparatus is simple. We place an electrode at the bottom of a tube from which it is insulated, and pass air with a whirling movement up through the tube, then causing the arc to strike in any convenient way between the electrode and the bottom of the tube. When an arc has been formed, the air current drives it up the tube, and it finally plays between the bottom electrode and the top of the tube, being thus a very long arc. It ends at a considerable distance from the insulated electrode, namely, at the spot where the gases become so highly heated by the arc that they have sufficient conductivity to allow the current to pass.

The construction of the furnace is shown in the diagram. At the bottom is the electrode A, which is insulated from the rest of the furnace. A heavy copper cylinder, water cooled, is employed, having an opening along the axis through which an iron rod, B, passes and projects. The rod forms the electrode proper, from which the arc springs, and it is the only part which is consumed, though the amount used up is small. The heat of the arc causes the end of the rod to become covered with a layer of melted magnetic oxide of iron, which is slowly volatilised. The rod at times is pushed up to allow for the wear, but it should be noted that the wear of the iron rods is too small to figure commercially in the process. The arc is started in the first place by an igniting rod, Z, a heavy iron rod leading from the mass of the tube, which serves temporarily as one electrode. Other methods, such as a fine wire, flame, &c., can also be used to start the arc.

The helical or whirling movement of the air is then produced in the inside of the apparatus, as will be further mentioned, and the arc is now formed throughout the whole length of the inner tube, having a length of 5 metres in the Kristianssand furnaces. The tube surrounding the arc is a simple iron tube, and the arc travels up to the top along this tube in the first place, but afterwards does not touch it, so that the tube is not eaten away.

At the top of the furnace is a special water cooling device, C, and by regulating the air supply we can make the arc rise up to this part. The helical movement of the air is given in a simple way by using a tangential inlet at the base. One such opening would give a screw-thread movement of the air around the arc from bottom to top, but using eight openings, E, greater steadiness is given to the current, and the arc is not deviated, but burns in a perfectly straight line. Over the air holes is placed a register ring, F, for regulating the air inlet. Two eye-holes, G, at the top of the furnace allow the upper part of the arc to be inspected. After having passed through the cooled upper end of the tube, the hot gases descend by the annular space between the metal part and the outer fire-brick portion of the furnace, and proceed thence through the outlet, O, to a common pipe, and thus reach the steam boiler, where their heat is utilised. While descending through the furnace the gases transmit a part of their heat to the inner tube, which they surround and through which the fresh air is brought in.

On the other hand, the air which enters the furnace at I goes first to the top, and takes up a part of the heat of the outgoing gases, as we have seen, then it changes its path under the



refrigerating part at K, and descends outside the tube containing the arc, thus continuing the heating. When it reaches the bottom, L, and is ready to enter the arc tube by the tangential openings, the air is now highly heated, as is required in this process.

After the first experiments at Ludwigshafen with a single 300 kw. furnace had been made, the next step was to build a larger plant at Kristianssand, Norway, so as to bring the process more nearly under commercial conditions. The plant worked very well from the start. It uses three-phase current coming over a 25,000 volt power line from a plant in the Saeters valley 18 miles distant. This is reduced to 7,200 volts for use in the furnaces. About 1,300 kw. is used for the purpose, employing three furnaces of 600 H.P. each. The company have also worked a 1,000 H.P. type of furnace with success, and expect to use it in future work. Even furnaces up to 2,000 H.P. can probably be built.

It is of interest to note that there is a consolidation of the various firms engaged in nitrogenous product manufacture. In fact, the Badische Anilin & Soda-Fabrik and several of its allied companies in Germany have made an association with the Norwegian Hydraulic & Nitrogenous Product Co., which owns the well-known Notodden works, as well as the Birkeland-Eyde patents. The united companies are to act in common for

Digitized by Google

developing the industry in Norway, and will use various sources of hydraulic power. At the present time a large plant is being built at Notodden in order to test large Schönherr furnaces, such as it is proposed to use as soon as the new Rjukan plant is finished. Should the tests prove successful, this type will, no doubt, be adopted finally for Rjukan, and it is here that the Birkeland-Eyde and the Schönherr processes will be used for the first time in common.

Concerning the Rjukan plant, this great enterprise is to furnish no less than 250,000 H.P. The work is now being carried on very rapidly. The formerly desert region of the Maana river is to be transformed into an industrial valley of the first order, which will utilise the admirable cascade of the Rjukanfos. No less than 3000 workmen are engaged in the hydraulic construction. The head of water will be used in two stages of 280 metres each, and two turbine plants will be erected at Saaheim, the first of which is to begin operations about the middle of 1911. It will contain 10 turbine-alternator sets, each with an aggregate output of 17,000 H.P., which will be used in the large nitrogenous product works near by. A railroad line, 30 miles long, recently built, and also a barge service on lake Tyn, whose length is 24 miles, will bring the products to Notodden (nitrate of lime, nitric acid, &c.), and thence they will be conveyed to Skien by river. Large depôts will be erected at Skien, and from here the transport to the Continent is by sea. After 1911 the company expects to turn out more than 100,000 tons of nitrogenous products annually. The united production of Notodden and Saaheim will thus be 130,000 tons in 1911, comprising nitrates and nitric acid. Besides this, the Badische Anilin & Soda-Fabrik has secured the falls of Matre and Tyn in the western part of Norway, and these will also serve to supply electric furnace plants, so that when these various projects are put in execution there will be more than 400,000 H.P used in Norway for the manufacture of nitrogenous products.

SAFE METHODS OF WORKING ON HIGH-PRESSURE WIRES.

[COMMUNICATED.]

A comparison of the methods of installation, maintenance and working upon what the Yankees call "hot" circuits is very often an interesting and instructive process, when these methods are English and American.

English superintendents do not like, nor are they allowed in many instances, to trust their men to work on "live" circuits when these circuits carry currents of a dangerous pressure. But it must be admitted a company is frequently very much handicapped when it has to shut down a particularly heavy circuit, thereby depriving a great many customers of service, when some trivial repair or connection has to be made.

A great deal of criticism has been called forth on American methods on account of the great number of deaths and serious burning among linemen and central station men, due to the way in which work has been done on such circuits, and the insecure protection these men have against accidents, for it is a common thing in that country to work on almost any sort of circuit. The linemen, naturally a rugged, rough hardened set, accustomed to take life lightly, are mostly not of a very high grade of intelligence, and therefore do not fear to do their work, not perhaps because of ignorance, but because of their familiarity with danger. But there are times when even the best of them will be caught.

Beyond the regulation rubber gloves and shoes nothing was done until the introduction of the Linemen Protector Shield. This device is shown in the accompanying illustrations (Figs. 1, 2 and 3). As will be observed, the apparatus is simply an easily applied extra insulation in the form of a rubber trough, called by the manufacturers the "Shield," which covers not only the "live" wires, but also the "tie" wires, and taps, if there are any. In the use of the shield each wire which a man may touch must be covered with a shield, excepting only the wire on which he is working.

In placing the shield over an insulator the lineman grips it by rubber handles attached to the outside of each one for this purpose, so that the shield is between his hands and the wire. He then slips a hard rubber split ring (having an opening of one-half inch or so to admit the wire) over each end of the shield. These rings clamp the shield firmly to the wire and preclude any possibility of its becoming dislodged and falling, to the danger of passers by.

This device is recommended by the manufacturers for use on all "live" or "hot" circuits at pressures not exceeding 7,500 volts. It is in use, however, on circuits of as high as 10,000 volts pressure. Before leaving the factory each shield is tested in water up to 30,000 volts. With pressures above 7,500 volts the maker thinks there might be danger to the man—no danger perhaps on a dry day, but on a damp day the static charge might spread along the surface of the shield and give the lineman a sufficient shock to throw him off his balance and cause him to come into contact with a highly charged wire, or perhaps fall to the street. The shield is made of pure para rubber, such as is used in the best quality of insulated wires.

At the time each of the accompanying photographs were taken the full power at 4,600 volts three-phase was on three of the wires covered by shields. The current was not shut off during any part of the time that the work was being carried out.

This device has been adopted by more than 200 electric light and power companies throughout New York and some other States. One company which has used these shields for the past two years reports finding them a time saver as well as a great protection to the

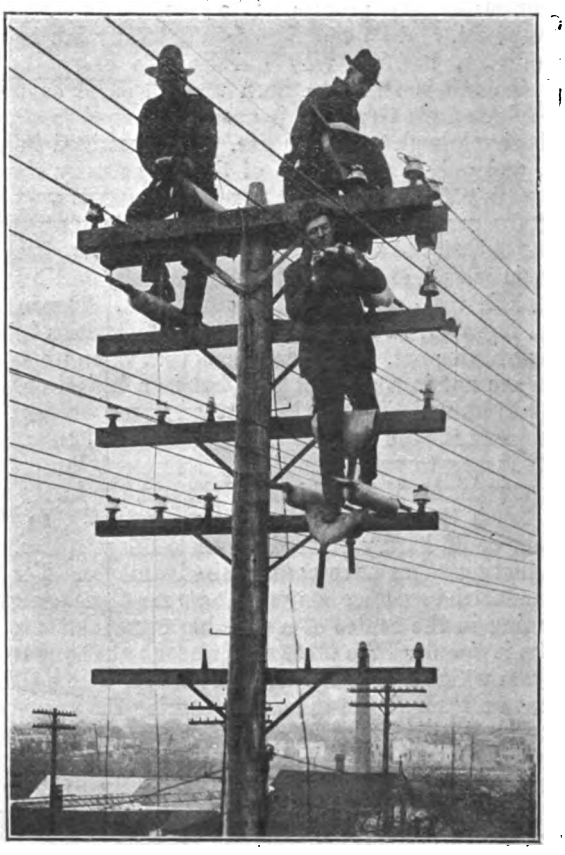


FIG. 1.—WORKING ON H.T. LINES, PROTECTORS IN USE.

men. Last April one of their foremen stated that they worked on 4,600 volt three-phase circuits under all weather conditions, and had not found it necessary to cut out any circuits in order to make taps, or do repairs to them, or shut down to move any transformers, during the 18 months which the shields had been in use. Prior to their use two men were killed within a year through short circuits while working on the high tension wires. Since adopting them they have not had an accident or a man burned while using them.

The device minimises the possibility of unintentional contact with other wires on the same pole, but, of course, does not do away with the risk entirely. The wire on which a man is working should still be handled with caution, and as an additional precaution it is wise to use rubber gloves in connection with the shield.

In the use of these safety devices there is the danger that the men will rely too much on them, and subject themselves to unnecessary exposure to "live" wires carrying an exceedingly heavy voltage. Having confidence in these devices, the linemen are tempted to do work on "live" wires which might, with a little planning, be performed when the wires are "dead"—in other words, the men may become over confident.

The manufacturers recommend three or four shields per wagon for use on single-phase circuits up to 2,300 volts, and six per wagon on all other circuits. It is a good plan to carry them in a

Digitized by Google

box in the wagon when not in use, so as to afford protection from wet, grease, or mechanical injury as far as possible. The shields cost £5 apiece, and are made by the Lineman Protector Co., of Detroit, Michigan. The Fidelity and Casualty Co., of New York,

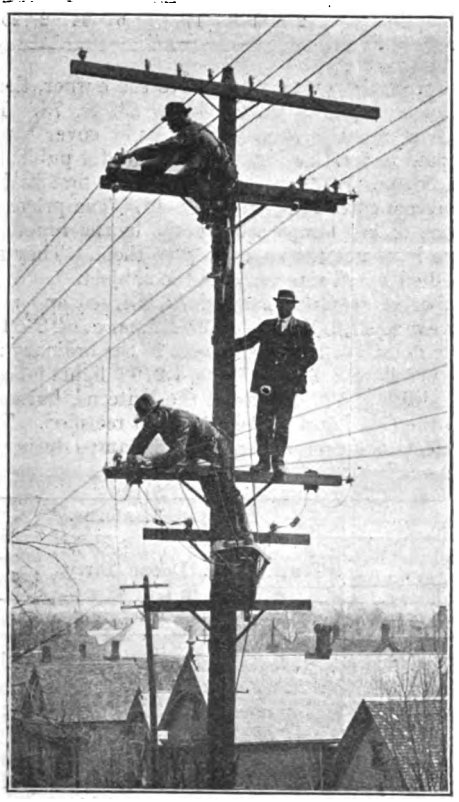

FIG. 2.—"SHIELDS" IN USE ON OVERHEAD LINES.

make it a rule to abstain from giving their endorsement to appliances of any kind. They depart from this rule in this case, because it is likely that the use of the given appliances would save lives. The greatest recommendation the American superintendents give it is

FIG. 3.—"SHIELDS" IN USE ON AN ARC LAMP CIRCUIT.

that it not only gives perfect safety to his men, but it enables them to perform their work better and faster, and at the same time effects important economies in time and money to the company.

We understand that the device will be placed on the English market shortly.

ANNUAL REPORT OF THE ENGINEER OF THE CITY OF LONDON.

In the annual report of Mr. Frank Sumner, engineer of the City of London, to the Improvements and Finance Committee of the Corporation, will be found many facts and figures relating to the "square mile" which should be of interest to our readers.

There is, first, the subject of public lighting, round which much controversy has raged, and a large amount of information is given about both the experimental and non-experimental types—both electric and gas. This part of the report reads:—

PUBLIC LIGHTING.

Electric Lighting.—The lighting of most of the main thoroughfares by arc lamps was continued throughout the year. The number of the original type "open" electric lamps in lighting at the end of the year, at a cost of £26 each, was 366, being a decrease of 32, accounted for by the substitution of the new and cheaper flame arcs in some of the thoroughfares. In addition to this number, there were 63 "Oliver" flame arcs (partly experimental), and 18 "Reason" enclosed arcs (experimental) in lighting during the year. These lamps were lighted on 18 days during the year when fog or unusual darkness occurred, at a total additional cost of £198. 0s. 5d. The number of defective electric lamps reported during the year was 52; deductions were made from the accounts of the City of London Electric Lighting Co. for such failures, which amounted during the year to £12. 9s. 2d.

New Flame Arcs.—A new rest being constructed in the carriageway of Gracechurch-street, opposite No. 40, the column lamp on the footpath at that spot was removed thereon, and an "Oliver" flame arc lamp, costing £17. 10s. per annum, was substituted for the "open" type of lamp, costing £26 per annum. The City of London Electric Lighting Co., on their own initiative, substituted an "Oliver" flame arc lamp for an "open" type of lantern on the rest at the southern end of New Bridge-street, by William-street, and 22 "Oliver" flame arc lamps were also substituted for open arc lamps in Old Bailey, Ludgate-circus, Ludgate-hill and St. Paul's Churchyard by the Company, at a decreased cost of £8. 10s. per lamp to the Corporation per annum.

The following table gives the number of arc lamps in lighting on December 31st, with the annual cost of the same:—

No. of lamps.	Description.	Price per annum per lamp.	Company.
366	Original type "open" lamps...	£26 0 0	City of London Electric Lighting Co.
53	"Oliver" flame arcs (partly experimental)	17 10 0	Ditto.
18	"Reason" enclosed arcs (experimental), Farringdon-st.	12 10 0	Ditto.
10	"Oliver" flame arcs (experimental), Cannon-street	17 10 0	Charing Cross Co.
447			

N.B.—The four "flame" arcs at Blackfriars Bridge Approach and the four at the Mansion House area put up by the City of London Company for their own experiment, and charged at £26 each per annum, were reduced in price during the year to £17. 10s. each per annum.

EXPERIMENTAL LIGHTING.

In accordance with the resolution of the Court of Common Council of July 25, 1907, whereby the two electric lighting companies having statutory powers in the City were permitted to experiment with the newest form of electric lamps for street lighting in the thoroughfares of Holborn, Holborn Viaduct, Old Bailey, Farringdon-street and Cannon-street (between St. Paul's Churchyard and Dowgate-hill), the Charing Cross & Strand Electricity Supply Co. have continued the lighting of their portion, viz., Cannon-street, with 11 magazine "flame" arcs, centrally hung, being suspended over the roadway by wires attached to the buildings on either side at a height of 28 ft. above the roadway. One lamp, at the corner of Dowgate-hill, was removed during the year owing to the re-building of the premises there. These lamps are charged at the rate of £17. 10s. per lamp per annum for the experimental period. The Charing Cross & Strand Company make this price conditional upon their having not less than 250 lamps to deal with.

The City of London Electric Lighting Co. have also continued their experiment with 21 "Oliver" flame arcs in substitution of a similar number of the original "open" arcs, adapting the existing columns in Holborn, Holborn Viaduct and part of Old Bailey, 20·5 ft. in height, whilst in Farringdon-street 18 enclosed arcs of the "Reason" type, fitted up on special short columns 14 ft. in height, in lieu of the

Back Lamps.	Columns.	Brackets.	Lantern.		Ordinary Burners.									High Pressure.						Special.	Total, 1909.	Total, 1908.
			Sq.	Cir.	3	4·25	4·25$^{1/3}$	4·25^{20} (Cubic feet per hour.)	6$\frac{2}{3}$	8·50	12·75	16	21·25	10	20	30	100	25 Inverted. (Cubic feet per hour.)	60			
63	540	2,117	2,624	96	10	1,978	41	484	1	57	5	2	1	45	45	2	1	17	6	24	2,720	2,730

12 "open" arc lamps and columns in that thoroughfare, have been maintained during the year. The installation of these two areas was completed by November 20, 1907. The maintenance cost of the "Oliver" flame arcs in the Holborn area is £17. 10s. each per annum, being equivalent to the charge for similar lamps in Cannon-street, and the cost of the enclosed arcs in Farringdon-street is £12. 10s. each per annum.

Gas Lighting.

The number of gas lamps (including experimental lamps) paid for by the Corporation at the end of the year was 2,720, being a decrease of 10 during the year. The size and character of these lamps are set out in the above table.

High-pressure Inverted Gas Lighting.—On October 15, 1908, the Court of Common Council agreed to the proposal of the Gas Light & Coke Co. to re-light Fleet-street and Chancery-lane experimentally by means of 17 high-pressure inverted gas lamps of the "Keith" type, on brackets fixed to the house fronts, projecting over the footpaths, in lieu of the 36 double-burner (upright) incandescent lamps on the footways, and the two high-pressure lamps on rests at the eastern and western ends of the thoroughfare, and on the convenience opposite Fetter-lane. This change necessitated the laying down of a 6 in. high-pressure main in the centre of the roadway, with branch services to each lamp, the pressure being 54 in. (water gauge), or 4 in. of mercury, which is obtained from the company's "power house" in Essex-street, Strand, the gas consumption per lamp being at the rate of 25 cubic ft. per hour, with an illuminating power of 1,500 candles; the inclusive annual upkeep of the lamps, with gas at 2s. 5d. per 1,000 ft., was £16. 10s. each. This charge was reduced to £16. 0s. 10d. on the reduction in the price of gas in June, and further lowered at Michaelmas quarter to £15. 2s. 6d. per lamp per annum when the price of gas was lowered from 2s. 4d. to 2s. 2d. per 1,000 cubic ft., the gas company providing the necessary compressing plant, mains, services, brackets and lanterns. The lamps, which were put into lighting on December 24, 1908, have been maintained during the year.

Other High-pressure Incandescent Gas Lamps.—There are 102 other high-pressure "Keith" gas lamps in the City thoroughfares, 42 upright single-burner lamps being fixed in the neighbourhood of Billingsgate on brackets. These lamps consume 10 cubic ft. of gas per hour, and give an illuminating value of 300 candles each, at a cost of £6. 13s. 6d. per lamp per annum. They are erected from 60 ft. to 70 ft. apart on the diagonal, at a height of about 12 ft. from the pavement level, and are fixed upon the house fronts, the roadway being about 50 ft. to 60 ft. wide. The lamps burn at 10 in. pressure from a special water-compressing plant placed in the adjacent pipe subway. The Corporation provided the compressing plant, services, lamp brackets and lanterns.

Forty-five upright two-burner lamps are fixed in Queen Victoria-street, each consuming about 20 cubic ft. of gas per hour, and giving a light equal to 600 candles, the cost per lamp being about £12 per annum. The lamps are fixed upon columns on the footpaths, about 100 ft. apart on the diagonal. The burners are 13 ft. 6 in. above the pavement, the street being about 70 ft. wide. The lamps burn at 10 in. pressure from a high-pressure trunk main direct from the gas-works; the Corporation provided the standards and lamps. There are also several other "Keith" high-pressure lamps, fitted with upright two, three, four and six burners, on rests at the junctions of roadways, of 1,000, 1,300, 2,000 and 3,000 candles, making 119 in all.

Low-pressure Inverted Burner Lamps.—During the year a trial has been made of the "Carpenter" South Metropolitan inverted burner lamp in Cheapside and Paternoster-row. Two double-burner lamps were fixed on the rests at the east and western ends of Cheapside, and a single-burner lamp at the corner of Paternoster-row and Warwick-lane, with satisfactory results. The consumption of gas per burner is 4 cubic ft. per hour, and the duty claimed is 120 candles per burner, or an illuminating value of 30 candles per cubic foot of gas.

Low-pressure Gas Lamps.—The number of low-pressure gas lamps at the end of the year was 2,601, principally consuming 4½ cubic ft. of gas per hour each, the illuminating power being 60 to 70 candles. Owing to the narrowness of the streets the lamps are chiefly fixed on brackets about 60 ft. to 70 ft. apart on the diagonal, at a height of about 12 ft. from the pavement level to the burner, the annual cost of each lamp with gas at 2s. 2d. being £3. 5s. 7d. This includes maintenance of mantles, &c., but does not cover capital charges. The prices paid to the Gas Light & Coke Co. for public lighting with gas was 2s. 5d. per 1,000 cubic ft. during the first half of the year. This was subsequently reduced to 2s. 4d. The prices paid for the various types of gas lamps are set out in the report, but, unfortunately, we have not the space to give them. They should, however, be studied by all interested in the subject.

The number of defective gas lights observed and reported upon during the year was 1,841—viz., 1,495 ordinary and 346 high-pressure lamps. The details of lighting defects in the ordinary incandescent lamps were as follows: Feeble lights, 1,276; lights failed, 20; total, 1,296. In addition, 199 defects in the lanterns, burners, &c., were reported to the Gas Light & Coke Co. and rectified. The details of the total defects observed in the ordinary lamps during the year are as follows:—

Defective lights.			Defective Lanterns.						
Feeble lights.	Lights failed.	Bottoms.	Tents.	Sides.	Doors.	Dirty.	Protectors.	Burners	Total.
1,276	20	25	9	30	2	66	55	12	1,495

The public gas lamps were lighted, in accordance with the general instructions in force for many years past, whenever fog or unusual darkness occurred. This happened on 38 days during the year, and entailed an additional cost of £150. 14s. 4d.

This part of the report concludes with the conclusions of the deputation that visited the Continent in the spring of the year to inspect the various systems of lighting. This has already been given in The Electrician.

Clocks.—It appears that of the 96 private clocks fixed above the public ways of the City only 31 are synchronised from Greenwich, though all clocks erected or overhanging the public way since 1903 have been synchronised.

Overhead Wires.—Since 1899, when the Corporation took over the duty of supervision, a total of about 25 miles of derelict wire has been removed. All overhead wires must be identified by a zinc label. One of the results of roof inspection is that large numbers of wires are found to have been erected in the City without any notice at all having been given; and it is only due to very careful supervision that new lines are detected. This will readily be understood when regard is had to the enormous number of overhead wires now fixed in the City, which continue to increase, and during the year the number of private owners of lines was 141, and the number of companies increased to 26. Both have considerably added to their number of spans during the last 12 months, and these now total about 733,956 spans crossing public thoroughfares, as compared with 733,828 last year and 260,000 in 1899. There has been a decrease during the year of about 220 miles of National Telephone Co.'s wires, chiefly in cables which have been taken down from the London Wall exchange, whilst other companies and private owners have added about 16 miles to their lines.

Special attention has been given during the year to the question of lines that contravene bye-law 4, under the Overhead Wires Act, 1891—*e.g.*, where they cross the roof of a building at less than 6 ft. in height. As most of the roofs of the City buildings have a trap-door or fire exit, any wire or cable fixed at a less height than 6 ft. would not only impede the progress of persons endeavouring to escape during fire, but would cause them injury, apart from the liability in the darkness of night to stumble of fall over the low parapets into the street or yards below. Many contraventions of this character have been dealt with, and the lines raised upon notification. The tendency of the National Telephone Co. is to take down their "open wires" and small cables, and substitute for them heavy cables; the larger and more recent contain as many as 400 wires, the number of wires thus increasing in a greater ratio than the spans. In 1909 26 companies and 141 private owners possessed overhead wires.

Notifications were given to the principal owners by the Corporation in 5,765 cases of broken wires and other contraventions of the bye-laws during 1909, as compared with 5,602 the previous year.

A matter of interest calling for notice is the use of aerial lines erected in the City for the purpose of intercepting wireless telegraphic and telephonic messages. During the month of September the British Radio-Telegraph & Telephone Co., of London Wall Buildings, Finsbury-circus, erected several such lines above the roofs of the before-mentioned building at a considerable height above the pavement. The lines have been put up by the Company for experimental purposes only. Two other companies came into existence during the year—*e.g.*, the Column Printing Co. (in connection with the "Central News" office), for the distribution of news to the Press, operating chiefly in the Fleet-street district among the newspaper offices. This company was formerly served by the National Telephone Co.'s lines; they have now their own plant and overhead system. Also the Intercommunicating Telephone Co., whose object is to connect up private firms by aerial lines.

DISCUSSION ON RAILWAY ELECTRIFICATION.

We give below an account of the discussion which took place on Friday last at the joint meeting of the Institution of Mechanical Engineers and of the American Society of Mechanical Engineers, when several Papers were read on the subject of railway electrification. Abstracts of the Papers read by Mr. G. Westinghouse, Mr. W. B. Potter and Mr. H. M. Hobart are given on pp. 677-689 of the present issue.

Mr. H. F. PARSHALL pointed out that both the New York Central and New Haven Railroads were handling a class of traffic that could not be handled by steam. He did not regard the New Haven Railroad as an electrical system, since the usual safeguards as to reliable operation had been most studiously eliminated and the system as it stood would not be operative in Great Britain. As regards Mr. Westinghouse's letter, the speaker considered it was erroneous to state that transmission was the principal element to be considered in respect to electric traction installations. Owing to the regulations of the Board of Trade in this country, the transmission system as a whole was a great deal more expensive than in the United States and the cost of the transmission system, including energy losses and capital charges, was about 15 per cent. of the total, as against 45 per cent. chargeable to the electromotive outfit, and 35 per cent. of the power station charge. The cost of the transmission system, even under the extravagant conditions obtaining in Great Britain (which did not obtain in America), was but one-third of the cost of the electromotive installation; and in applying the differences commonly recognised and proved, the difference between single-phase and continuous-current motors would more than wipe out the whole 15 per cent. in the transmission system. Further, if the energy were transmitted single phase, the cost of copper in the single-phase system, with the same power factor, would be one-third more for the alternating-current system than for the direct-current system. Allowing for 10 per cent. additional loss for the rotary converter of the direct-current system, for equal current density, the cost of copper with 0·75 power factor would exceed by 60 per cent. that of the direct-current system, and for equal energy loss would be double that of the direct-current system, always on a basis that the alternating-current train outfit was as efficient as the direct-current outfit. The characteristics of the collector system were only determinable from the nature of the service worked. Distance was only a factor in so far as the transmission system was concerned, and the transmission system in the case of a single-phase system was heavily handicapped. Further, owing to the compensating properties of the rotary converter, in a general system it would justify its existence, considering the material economy effected in having unity power factor in the transmission system. He did not attempt to analyse detailed figures, but pointed out that these naturally would be prepared with reference to conditions that could not be taken into consideration in a general discussion of the kind. In conclusion, he stated that the continuous-current system was the only one known in the present state of the art that could compete with steam in the classes of installation to which electricity was generally applicable, that is, to urban, suburban and dense interborough traffic.

Mr. J. DALZIEL (Midland Railway) said that both the English Papers before the meeting asserted that main line electrification was commercially impracticable, and that suburban working might therefore be dealt with quite aside from any main line considerations. While he did not agree with this view, he considered it more reasonable than that advocating separate consideration of every case. That course, to his mind, spelt chaos. He believed that main line electric working in this country was not only commercial but comparatively imminent, and if that was so, it was unquestionable that—other things being equal—to design to fit in with those future conditions was more important than anything else in scheming any electrification, and that therefore the finding of a generally applicable all-round system was the most important traction problem of the day. He took up that position in his joint Paper to the Institution of Civil Engineers last winter, and followed it out to show by the results of tests that the single-phase system was burdened with few if any of the disabilities attributed to it, more particularly in suburban work, and that—other things thus being equal—it emerged as the desired generally applicable system. According to the present Paper, that was also Mr. Westinghouse's opinion, and it also represented, apparently, that of Continental engineers, whose adoption of the single-phase system, particularly in Germany for heavy working, was almost universal. The tendency at the conference of the International Railway Congress within the last few weeks was towards a similar conclusion. Even granting that the single-phase system had disadvantages in suburban work, he did not see how electrification could be regarded as a narrow question of separate sections and districts. Leaving aside detail, into which he had entered elsewhere, the same policy necessarily evolved to meet the continuous growth of traffic that had led to doublings, widenings, and re-gradings pointed directly to electrification, and without information as to the existing railway conditions it was impossible for any correct judgment to be formed as to the actual demand for increased capacity. It was clear that with all the doublings and widenings that had taken place there must be lines which were approaching their maximum capacity; and where expensive methods, such as double heading, banking, and so on, were required, that the necessary increased capacity on those lines could be obtained far more cheaply by electrification than by doubling or re-grading. For example, though he made no allegation as to congestion on the lines in question, and spoke not at all for the Company with which he was connected, the disparity between the relative costs of electrification and of re-grading alone without doubling on the Derby-Manchester and Sheffield-Manchester sections of the Midland main line would clearly be overwhelmingly in favour of the electrical alternative. It was true there were no water powers in this country, but there was coal of cheaper quality than could be burned on a locomotive, and, in fact, electrification schemes on those very lines were in progress in Germany, while the heavy, continuous and mixed traffic, the large amount of shunting and terminal work, and the congestion and heavy grades of many sections and branches were factors favourable to electric methods here more than anywhere. To ignore main line work, then, would be to take a very serious risk of incurring future complications and retarding natural development, and that being so, single-phase in suburban work must have drawbacks very pronounced indeed to justify its being discarded. The English Papers before the meeting were adverse to single-phase, but the allegations made earlier in its history of inferior acceleration and higher power consumption for similar schedules had disappeared. There remained adverse weight and cost comparisons and unreliability. Mr. Potter's reports as to unreliability probably resulted to some extent from the double current working so largely used in America, which, by the complications it introduced, and which they hoped to avoid here, undoubtedly must reduce reliability as well as increase both cost and weight. Single-phase apparatus being new, progress in knowledge and design would assuredly reduce both weight and cost. In respect to reliability, and in particular to Mr. Carter's remarks as to the use of forced draught, he would like here to interject that the Midland's Westinghouse single-phase equipment at Heysham had had only four breakdowns in the 2½ years of its service; and these being caused by failures respectively of a lightning arrester, a badly made high-tension joint, a circuit-breaker trip coil and a motor armature, could hardly be attributed either particularly to the fact of the apparatus being single-phase or in any way to forced draught being used. With regard to efficiency, the lower single-phase efficiency was counterbalanced by the single-phase motor characteristic being better suited to heavy schedule suburban service because of its better sustained acceleration, a feature which might be accentuated by over-voltage tappings, and which increased coasting and decreased brake losses. In fact, cases in which the actual power station output or purchased energy for the railway were so appreciably greater with single-phase as to justify its being passed over if there was any possibility whatever of long distance extensions, were, notwithstanding the greater equipment and train weights, practically non-existent, and in most cases the single-phase should go in on its merits anyhow. Taking one example only, Mr. Aspinall's Liverpool-Southport trains had a consumption of 96 watt-hours per ton-mile. On a similar schedule the Midland Heysham train consumed on test 88 high-tension watt-hours per ton-mile with a very light train. With trains of similar accommodation, the respective power station outputs would be as 1·25 (direct current) to 1 (alternating current), the latter train being 3·8 per cent. the heavier, making no allowance for better working of the longer train. That schedule could be maintained by the alternating-current train continuously. He would like to say that Mr. Carter's direct-current efficiency in Fig. 5 was 93½ per cent. overall, so they must be specially good motors. He could not follow Mr. Carter's anti-forced draught remarks, as forced draught was being increasingly adopted and involved no difficulties not easily got over. Why not take single-phase motors, like other things, as they were? What he had to say on Mr. Hobart's Paper hinged largely on Table I. In the first place the Heysham trains were not primarily designed for the service analysed by Mr. Hobart. They took occasional loadings much in excess of those given, the Midland working time-table permissible loads being 400 tons between Heysham and Morecambe, and from Morecambe to Lancaster, and 185 tons Lancaster to Morecambe. On busy days in summer the cars took four coach trains for many hours together as rapidly as those trains could be got in and out of the stations, and that service was principally between Lancaster and Morecambe, which was a shorter distance and a higher speed schedule, being less restricted by curve restrictions than that in Table I. What those coaches were fully capable of doing might be typified by the 30 miles per hour 1·32 mile service with 88 watt-hours per ton-mile consumption already mentioned. Using with those the revised Siemens equipment weight he had made up another analysis of the Heysham train bringing out the correct horse-power per ton of electrical equipment at 8·83. Those figures were

Digitized by Google

available to Mr. Hobart, and could have been used. A fair comparison on actual weight of the schedule he had used should have been based on the Westinghouse car, the equipment of which gave an output figure of 7·2 H.P. per ton. That, however, by no means ended his criticism. As Table I. was a comparison really of continuous output capacity and still remained one in which a forced draught motor made a worse showing than the naturally ventilated one, it was evident there was something still wrong. As a matter of fact, there must be a mistake in the ton-mile consumption given for the Piccadilly train. By a set of simple calculations which he, the speaker, had put in, and which were open to Mr. Hobart's criticism, it was easy to show that on that input the mean current input per motor was of the order of 95 amperes, so that the root-mean-square current per motor could not be less than 150 to 200 amperes, or the unheard of figure for a naturally ventilated motor of half to two-thirds of the one-hour rating. The Piccadilly consumption and that given for that schedule by Mr. Hobart in his Table VII. were entirely in disagreement with the consumption figures for that and like schedules in his own book, "Electric Railway Engineering." On pages 77 to 80, diagrams 90 and 94 to 96 of that book, practically that very schedule was given as requiring only a consumption of 56 watt-hours per ton-mile with 32 seconds coasting, up to 72·8 watt-hours with no coasting at all, that was the absolute maximum, the consumption being reduced on the track graded for acceleration and retardation to 30·7 watt-hours. The Piccadilly line was described in the tramway and railway world as graded, but the question of grading was extensive. He found by observation that coasting between the shorter distance stations averaged about 38 seconds, which would therefore make the working of the line correspond, even if level, to certainly no more than the above-mentioned 56 watt-hours per ton-mile. Giving Mr. Hobart for tunnel train resistance, which, according to his footnote on page 26 of his Paper, should not have much effect, an increased allowance up to 63 watt-hours per ton-mile, and revising his figures accordingly, his specified figure for output per ton of the Piccadilly equipment became 7·4 against the specific output of the Heysham train, already mentioned, of 8·8. Such a result was only to be expected in consideration of forced draught being in use on the latter. That corresponded to a root-mean-square current on the Piccadilly train of about 90 to 120 amperes, which was quite high enough.

Mr. SIDNEY STONE said that one very important thing in connection with electric traction had not received very much attention. He referred to the wear of the track, and he had rather hoped to have heard something from his American friends as to their experience of track wear. He believed it was a fact that the wear of the track on electric railways in this country was excessive, more particularly on those lines using the multiple unit system. On the City & South London Railway, where they had an electric locomotive, wear of track was not so marked, but on the other lines—more particularly on the District Railway, where they used long trains with probably three motor coaches, the wear was very marked. It had occurred to him that probably they had not looked quite at the right point to ascertain the cause of the wear. He had noticed when travelling on the District Railway how the rails were worn pretty regularly, the worn spots being about 40 ft. apart. Apparently the bogies were wearing and digging into one side of the rail until they met sufficient mechanical resistance to throw them over to the other side. He thought the cause of the wear, more particularly on the multiple-unit system, was due to the fact that the trains were running with a motor at either end, and when on a curve there was an increased mechanical resistance at the front coach causing frictional resistance on the rail. The motor at the rear of the train did not meet with the same resistance, with the result that it pushed the train up and out of line, particularly on curves or up gradients. With a locomotive which was always keeping tension on the draw-bar, the trains were pulled along the rail all the way through. If multiple-unit trains were to be used successfully then the power on the front motor would have to be increased, so that there was always tension and never compression on the draw-bar. He had some time since suggested a method by which the maximum propelling effort would always be obtained form the leading motor whichever way the train was running.

Mr. C. F. SCOTT (Past-President of the American Institute of Electrical Engineers) said that the range of the Papers had brought out one thing, viz., the breadth of the subject and the variety of conditions. He might almost add with regard to railway electrification that there were no general rules. In every case the various elements entering into the question, such as length of line, density of traffic, character of traffic, gradients and speeds, were all factors that had to be considered as a whole, not separately. Consequently, generalisations were very apt to lead to very peculiar results if applied to any specific case without modification. They were apt, also, in some of their engineering discussions on the other side of the water, to devote most of their energies to controversies as to the systems rather than to considerations as to the general features of railway application. Electricity had a way not only of doing the same things that had been done before and often doing them in a better way, but also of introducing new methods. Upon looking at the literature of 20 years ago regarding the electric motor one would find that it was largely a comparison of the relative power required, or the relative efficiency of transmission by shafting and motors. They all knew that the reason for using electric motors now was not that they might save power, but that they might be able to use more power efficiently and to secure the advantages of speed control, readiness of operation, reliability and convenience which the electric motor afforded. It had been brought out in the Papers that the increased capacity of a railway line at congested points by double tracking or other increase in track facilities might be secured by electric traction. New possibilities were also open to railway terminals. A railway terminus at the present time with many tracks utilised a great breadth of area in centres where ground was extremely expensive. Electrification, however, permitted double tracking, or even treble tracking of railways, so that the same number of tracks could be got one above the other into a very much less space than was now utilised. He mentioned that simply as an illustration of the kind of thing which electric traction might bring about. The construction described in Mr. Westinghouse's Paper in which the electric motor was shown placed well above the driving axles, the driving being by side rods, although used on the Continent, was quite new to America. The locomotives used on the Pennsylvania Railroad had very large motors in the cab, and he believed that those locomotives were the largest ever made. A new locomotive used on the New Haven Railroad was of interest, as each motor was mounted directly over the axle which it drove, the drive being by gearing at each end. The latest locomotives made for the New Haven line had been designed for both passenger and freight service. In regard to the comparisons that had been made between the direct-current and single-phase systems, he did not intend going into any detail, but merely wished to bring forward some general comparisons between the two systems. It had been quite properly brought out in the Papers that the real difference was that the single-phase equipment cost more and that the advantage of the single-phase system was in the lesser cost of the line. The need of careful observation of those considerations, and also of noting carefully the specific conditions in particular cases, was brought out by examining some of the figures which had been set out in the various Papers, and showing the different conclusions that might be drawn from a slight change in conditions or assumptions. In Mr. Hobart's Paper two elements were considered, the first of which was the equipment. That element had been taken up by previous speakers, and, moreover, he was not competent at the present moment to discuss it; but upon looking at the Paper generally he found that the other element was transmission, which was by some recognised as the large element to be considered, and was certainly a most important one. This had received almost no consideration. Mr. Hobart passed all that over by a statement giving the cost of electricity at the car as 0·9d. for direct current and 0·72d. for single phase, the former figure being 25 per cent. greater than the latter. That was the cost of power at the car, irrespective of the efficiency of the car itself. The losses in the direct-current system were greater than in the single-phase system between the power house and the car. The average all-year efficiency of a sub-station varied through a wide range, depending on the size of the sub-station and the load factor. For general average conditions he believed that an efficiency of about 80 per cent. for the sub-station would not be too high. In some cases it might be higher, and in some cases he knew it to be lower. One would not be very far wrong, therefore, for a general comparison if one said that the amount of power generated for the direct-current system was 25 per cent. greater than for the single-phase system for each kilowatt-hour delivered to the car. That was the ratio which Mr. Hobart had taken, allowing nothing for the greater first cost of the direct-current sub-station or for the operation of the sub-station. Those elements would evidently increase very considerably the cost of direct-current power. In Mr. Pomeroy's Paper some figures were given concerning the New York Central Railroad. He quoted Mr. W. J. Wilgus to the effect that the total cost of power was 2·60 cents (1·3d.) per kilowatt-hour. Of that amount only 40 per cent. was charged to the power station and 60 per cent. to the transmission and sub-stations. That showed that in a system where the transmission was within a radius of about 10 miles the cost of transmission and distribution was a very important item compared with the initial cost of power. Taking the cost of the sub-station part for alternating-current as about one-quarter of that for direct-current sub-stations, one obtained as a result a ratio which showed the cost of the direct-current power to be not 25 per cent. greater, but 50 or 60 per cent. greater than the cost of single-phase power. If those figures were applied to Mr. Hobart's Paper there would be quite a material change in the results. Hence, slight differences in assumptions might make very considerable differences in results. In regard to Mr. Carter's Paper, he noticed a statement to the effect that although both motors were dynamically capable of working the service, the direct-current motor alone had sufficient thermal capacity for the purpose, the other having to dissipate three times as much energy as it could get rid of by natural cooling. The speaker thought that that certainly could not be taken as a general statement applicable to all single-phase motors, for it would be impossible to work them if they were generating in themselves three times the heat that could be dissipated. Possibly, he thought, there might be some slip in the statement, but on the face of it the low efficiency attributed to single-phase motors was absurd, as was shown by the daily operation of these motors. Mr. Potter, in his Paper, gave some interesting figures for interurban electric service which the speaker would like to consider from two points of view: firstly, as to the figures given and assumptions made, and, secondly, as to the completed systems. He did not intend going into certain minor points about which he believed there would be some ground for discussion. For example, he noted that the maximum speed of the single-phase motors was given as 35 miles per hour, and that of the direct-current 48 miles per hour. He believed that requirement was excessive for the service, and would impose serious restrictions or extra cost on the alternating service. The speaker also noticed that the electrical maintenance for alternating current was given as 1½ cents (0·75d.) per car-mile. That, however, differed greatly on different roads, and in considering a system one ought to give due consideration to what could be done under good conditions as well as what could be done under all sorts of conditions. Taking the oldest single-phase

Digitized by Google

line running, the electrical maintenance over a period of three years had averaged less than a cent (0·5d.) per car-mile as against 1½ cents (0·75d.), as given in the Paper. A correction had been made by a former speaker in the cost of the cars, reducing that item by something over $50,000 (£10,000), owing to a misprint, and he, the speaker, thought other reductions should also be made both in the cost per equipment and in the number of equipments. The road referred to was one which required six cars in service at one time. How many cars should be purchased in order to maintain six in service? That was a question of judgment and experience, but he thought they would all agree on one thing, viz., that the figure given in the Paper was excessive. Fifteen direct-current cars had been provided, meaning that nine cars were to remain idle, and for the single-phase cars the requirement was that for every car required in service two would be idle, making a total of 18. If the number of cars was reduced to, say, 10, each allowing two-thirds of the number of cars in service to lie idle, the car costs would be brought down very much, and by using the figure of $17,000 (£3,400) per car without question (he would reduce it somewhat) they would then have a very material reduction in the cost of cars, which was the largest item in the final summary. That would bring the total cost of the two systems very nearly equal. His point, therefore, was that slight differences in assumptions, and changed assumptions which were apparently not well founded, made very radical differences in the final results. The speaker then compared the capabilities of the two roads. The requirements for 1,200-volt direct current were that the line should be sufficient for starting one car and running one car at the momentary maximum demand between stations. As the stations were 28 miles apart, and as the conditions were substantially the same over a considerable distance there was therefore a distance of 10 to 14 miles for which the limit was the starting of one car and the running of another. Literally, therefore, two cars could not start without exceeding the maximum allowable momentary demand between the sub-stations. The alternating current was about on the same basis. Two cars might start between sub-stations, but the sub-stations were further apart. That meant that the cars must be kept one hour apart, and it seemed practically to bar all trailers, and any two car trains or extra cars. If three cars should get on one section at once that section would be overloaded, and the greater the overload the lower the voltage, and consequently the lower the speed of the cars. That could be remedied by increasing the line capacity. They could double the capacity of the line by doubling the number of sub-stations, but in one case the single-phase sub-stations cost only $20,000 (£4,000) while the direct-current stations cost over $100,000 (£20,000). The single-phase sub-stations had an annual maintenance of $600 (£120) and the other $3,200 (£640) as given in the Paper. In that typical interurban service, therefore, he would point out that the rolling stock had been put in to an excessive amount, whereas the line capacity had been put in at a minimum. They must, therefore, in comparing systems of that kind, give due consideration to those two elements, as it was not wise to provide three times as many cars as the line was able to supply current to, nor, on the other hand, was it wise to make the line capacity so small that it could not operate any cars in addition to the regular schedule when desired. In conclusion, the speaker referred to the fact that the earliest single-phase road, which was originally 40 miles in length, had been extended to over 100 miles, that its schedule speed was higher than any other interurban road, and that a recent official report showed the cost per car-mile to be less than that of any of the direct-current roads which traversed the same State (Indiana) and operated under substantially similar conditions. Moreover, the only distinctively heavy electric trunk line service in America, as distinguished from terminal and tunnel service, was on the New Haven road by the single-phase system; and, furthermore, this was the only road which was now actively proposing to extend its present electrical operation, and this extension would employ single-phase apparatus.

Mr. PHILIP DAWSON, in a telegram, which arrived at this juncture and which was read by the secretary, regretted his unavoidable absence, particularly as Mr. Hobart's fundamental data regarding the South London Elevated train were quite wrong. The weight of the equipment was 36 tons, not 44 tons; the energy consumption per ton-mile was 66, not 79 watt-hours; and six motors were quite satisfactory to run the service. Those errors alone vitiated all Mr. Hobart's conclusions.

Mr. H. M. HOBART made a few comparisons in connection with Mr. Potter's Paper which he thought might be of interest. Mr. Potter and himself seemed to be in good agreement on many points, but on the whole, in running through the various data, it was his (Mr. Hobart's) opinion that the cost of the continuous-current system, as given by Mr. Potter, was a little lower than his own data and that of the single-phase system a little higher. The result of running the figures so close was that it would take very little alteration in them to change the balance in favour of the single-phase system. His conviction was that in the case of the 100-mile line referred to, the single-phase system would be the cheaper and the more appropriate, though the difference would be very slight indeed. He had hastily compared the cost by taking the cost of the cars per ton weight. Thus $17,000 (£3,400) was high for the alternating current car, or, taking the relative figures, $10,000 (£2,000) would be low for the continuous-current car. The cost per ton for the continuous-current car worked out to £64 and the single-phase car to £89. Assigning to the single-phase car so much higher a first cost it was unreasonable to give it a life of only 12 years as against a 15-year life assigned to the car equipped with continuous apparatus. He thought that the balance would be in favour of the single-phase system for that line, but pointed out that such a line with only one train per hour was a case for steam, and could not be operated electrically at a profit unless the receipts per seat-mile were far greater than could be obtained in this country.

Mr. A. SINCLAIR referred to the question of extending electrical operations to freight service. Mr. Westinghouse thought that would gradually be done, but so far as the speaker's experience had gone with railway operating he did not think there was the least indication of such a thing. No such drastic change should be made without considering all possible difficulties. From what he had seen of railway operating in the United States the chances for electric traction for freight were very small indeed.

Mr. J. G. WILSON criticised what he took to be the keynote of Mr. Westinghouse's Paper. Mr. Westinghouse advocated the adoption of one system of electric traction to the exclusion of all other systems. From the point of view of those railway companies owning routes capable of profitable conversion to electric traction, three facts had so far been established from the actual results of electric traction. Firstly, on suburban routes with heavy and moderately heavy traffic, conversion to electric traction was capable of effecting a considerable reduction in working costs, even taking into consideration the capital that had to be spent. Secondly, the adoption of electric traction on suburban routes gave the only really effective and satisfactory means of competing with other systems of suburban traffic. Thirdly, there were inter-urban routes, and possibly, also—with all respect to Mr. Sinclair—there might be cases of exceptionally heavy freight movement where the adoption of electric traction might offer advantages and possibilities. Progress might have been more rapid but for the fact that there were at least two proven methods of making the conversion. The fact that there were two methods could not but perplex the railway man, and Mr. Westinghouse, in order to remove that bar to progress, advocated the adoption of one system of electric traction to the exclusion of the consideration of all others. The speaker was in entire agreement with Mr. Westinghouse so far, provided, of course, that such a thing were practicable. It would have many desirable results, but he (the speaker) could not escape from the conclusion that such a course was impracticable; moreover, it is not absolutely necessary, though desirable, and, further, it was not economically sound. As an example of the difficulties, he took an illustration of two railways entering London. One of them, the Great Eastern Railway, had what was certainly the heaviest and most important suburban traffic in the United Kingdom. The other, the Great Northern Railway, had a very small suburban traffic, but was an important mineral line on which the consideration of electric traction might crop up in the future. It could be shown that the cheapest method of dealing with the suburban problem on the Great Eastern Railway was by the adoption of the direct-current system; but for anyone considering the problem of the Great Northern Railway's mineral traffic it would be impossible not to take into consideration the claims of the single-phase system. If one of those railways, for the sake of interchange of traffic, was going to give way to the other, which was it to be and what inducement could be held out to the railway company which gave up any immediate advantage in the matter? He did not think it could be too emphatically insisted on, for the sake of the railway companies, that whereas the one system could not be adopted in all cases, yet in any individual case the cheapest and best system could be adopted with a great degree of certainty. Lastly, he did not think that to delay the conversion to electric traction for the sake of uniformity was commercially sound, because the advantages to be gained by uniformity were remote and problematical, whereas the advantages which in the meantime were being forgone were real and too large for a railway company to forego.

Dr. F. R. HUTTON thought there was no question that electrification was of great importance where there were a number of cities close together such as in this country, but the conditions in the United States were quite the reverse.

Mr. F. W. CARTER, in reply, said that Mr. Dalziel had referred to the question of efficiency. He (Mr. Dalziel) mentioned an efficiency of 93½ per cent., but the speaker did not quite know how he had obtained it. If he had referred to the efficiency of the motors, exclusive of the gear and friction losses, the figure he had mentioned was about correct for the continuous-current motor whose characteristics were given; in fact, the average value of this efficiency whilst running at full voltage was probably nearer 94 per cent. Mr. Dalziel had also suggested that he (the speaker) could have improved the showing of the single-phase motor if he had chosen different gear so as to get the same free running speed for the two motors. Mr. Carter did not think the free running speed was a matter of any particular importance, because that speed was never reached. The reason that particular gear was chosen was in order to obtain the same margin in the schedule and thus to give equal capacity for making up time with the two equipments. In connection with Mr. Scott's remarks, all he had wished to say in the Paper was that the single-phase motor whose characteristics were given was dynamically suitable for the service, but that it could not be used for the service unless forced draught were adopted to the extent necessary to carry off the extra heat. As a matter of fact, the continuous-current motor was run at about the limit of its thermal capacity with natural cooling.

Mr. H. H. BARNES, JR. (New York), in replying to the criticism on Mr. Potter's Paper, said that Mr. Scott had remarked that the number of cars shown for the three classes of equipment was excessive. As shown in the footnote the figures of the miles per car in service per day and the miles per day on the average were taken from present practice on the other side of the water. For the sake of argument, however, they might admit that the figures were low, and in order to illustrate where they would come out by a radical change, he had thoroughly checked the

Digitized by Google

figures on the basis that instead of 15, 15 and 18 cars they only had half that number. Upon halving the number a condition was obtained under which the route could not be operated; but, nevertheless, on that basis he found approximately, that the difference in the annual cost of operation, consisting of fixed charges and the operation and maintenance charges, instead of being £6,400 in favour of the 1,500 volts, would drop to about £4,000. In other words, the cost would go down faster in the case of the alternating current, but it [still] left £4,000 in favour of the direct-current system. That represented about 14 per cent. on the actual total annual cost. Another point which had a bearing upon the total figures, and referred to by Mr. Hobart, was that of maintenance, the figures for which were considered rather high. The figures given, however, represented reasonable averages, and he thought that the brush maintenance (to take one feature of the maintenance only) in accordance with their experience between alternating current and direct current was about as 100 to 1 against the alternating current. As far as he was aware, also, the actual number of men employed for a given service on alternating-current lines, even though they had not any sub-stations, was as great; or greater, than on the corresponding direct-current lines with their sub-stations. The amount saved in the sub-stations was needed in the bonds. In conclusion, he again emphasised the fact that the table in the Paper was based upon conditions which were recognised as unfavourable to the direct current. That was done in order to give the alternating current as fair a showing as possible. Under more favourable conditions the improvement would be more marked.

Mr. J. A. F. Aspinall was very glad to see in Mr. Westinghouse's Paper the diagram illustrating the new electric locomotives that they were constructing for the hauling of their heavy electric trains. They very soon realised on the Liverpool and Southport line that if heavy electric trains were to be hauled and that if the cost of repairs to the motors and motor trucks was to be kept down they would have to revert to the large bearing surfaces used in locomotive practice, which experience had shown them to be necessary in any hauling machine. The practice which they were now establishing in the United States got over the difficulty of low centre of gravity of the motor trucks in the multiple unit trains and of the weight not being spring-borne, this being the cause of excessive wear and tear of the rails. The experience of four or five years' running on the Liverpool and Southport line had shown that the electrical system, such as they had, was perfectly satisfactory. One speaker had touched upon the great diversity of opinion between electrical engineers. As a general manager of one of the English railways, he thought that no general manager could afford for one moment to close his eyes to the possible utilisation of either one or the other system, whichever might prove to be commercially right, and the utilisation of the rolling stock to its greatest possible capacity was one of those items to which much greater attention must be paid than to almost anything else. He was, therefore, pleased to see in Mr. Pomeroy's Paper a diagram illustrating in a very clear manner what a very small proportion of the time of a locomotive, whether steam or electric, was occupied in doing useful commercial work, that 22 per cent. of the time was spent in the shops in repairs and maintenance, that only 28 per cent. of the time was commercially used, and that 50 per cent. was wasted in waiting at terminal yards, side tracks, &c. There was more money to be made out of that little diagram than in all the variations of system.

THE LATEST G.E.C. "WITTON" SWITCHES.

The General Electric Co. have recently placed upon the market a complete line of chopper type switches—to be known as the "Witton" type—which are manufactured throughout at Witton

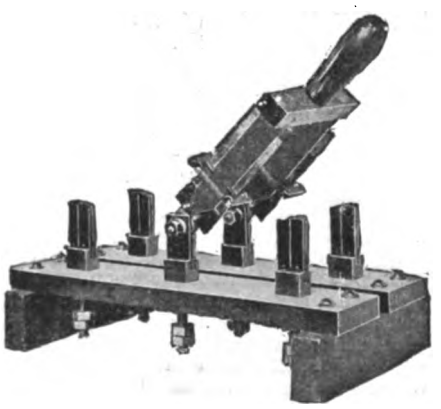

Fig. 1.—Double Pole Change-over "Witton" Switch.

Works. The switches are made and stocked for maximum currents of 30, 60, 100, 200, 300, 400, 600, 800 and 1,000 amperes, while any larger capacities up to a maximum of 10,000 amperes capacity can be made up at short notice. The advantage of the many sizes is evident, if one considers that it does away with the necessity of paying for, say, a 600 ampere switch when the maximum current is only 350 amperes, because the 600 ampere switch happens to be the nearest larger size.

The same general design has been carried through the whole range, and the appearance of the switches of different capacities is therefore similar, an obvious advantage which will be readily appreciated by switchboard makers, as it certainly improves the appearance of a switchboard if the apparatus mounted thereon is of uniform type.

The switches are amply dimensioned, the current density nowhere exceeding 1,000 amperes per square inch sectional area, and 60 amperes per square inch surface area in the contact clips. With regard to surface density, it is claimed that these switches are the most amply rated of any obtainable; this is a decided advantage as most losses in switches are due to insufficient contact surface in the clips. Moreover it allows of the switches being overrated as much as 50 per cent. permanently without dangerous heating, and much higher for short periods. This may be very desirable in an emergency.

The accompanying illustrations show sufficiently the general design, and it is only necessary to point out a few details. For instance, the flipper blades, which give the quick break, are fitted with a steel stamping where they are hinged, and the main blade is bushed with a steel bush for the hinge pin, which makes the actual wearing parts very strong. At the handle end, the main blades, up to and including those on the 200 ampere size, are provided with pressed steel clips to which the handle or, in multipole switches the bridge is attached. Over this size solid square steel ends are used. To hold the blade in the "off" position in change-over switches, or where there is no room to swing the switch right over, shaped steel springs are provided, which are fixed to the side of the hinge contact, and

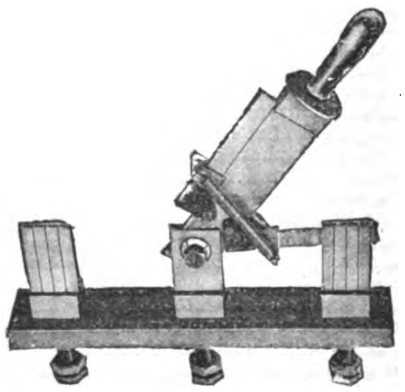

Fig. 2.—Single Pole Change-over "Witton" Switch, Showing Flipper Blade.

act on the rounded end of the flipper blade pivot pin. The switches are stocked in the "single," "double" and "triple" poles type, and for either front or back connections. A larger number of poles can be made up on short notice. The switches are jig made and all parts are interchangeable. The finish is copper and black.

LEGAL INTELLIGENCE.

Attorney General (ex. rel. India Rubber, Gutta Percha and Telegraph Works Co.) v. West Ham Corporation.

Mr. Justice Neville, in delivering judgment in this case on Friday last, said the statutory powers of the defendant Corporation included the supply of electricity and electrical fittings, and they had been entrusted with extensive powers of borrowing, to be exercised with the sanction of the Local Government Board. They had 10 different accounts at their bankers, into one of which, the general account, they paid all receipts on account of the borough fund and the general district rate, and upon which they drew in respect, amongst other things, of their expenditure upon their electrical undertakings. The Corporation kept in their books two electricity accounts, one called the capital account, dealing with expenditure on fixed capital, and the other the revenue account, which, besides showing the surplus or deficiency on the year's working, included their expenditure on electrical fittings and stores. For the latter they had borrowing powers, to be exercised with the sanction of the Local Government Board, but they had not, on March 31, 1908, obtained any such sanction. Any deficiency upon the year's working was estimated for in the rate for the following six months and levied; but no estimate was made in respect of the capital expenditure upon the electrical undertaking, whether fixed or floating; this was found either from other funds of the Corporation not properly applicable for that purpose, or by overdraft from the bank. On March 31, 1908, the overdraft on the electricity revenue account was over £44,000 and on the capital account over

Digitized by Google

£92,000. In my opinion these overdrafts were illegal. On April 15 sanction was obtained from the Local Government Board for a loan on electricity capital account of some £64,000. Towards the end of 1905, by this and other expenditure made for legitimate purposes, but which was intended to be met out of funds to be produced by the exercise of their borrowing powers, and for which, consequently, no estimate was made or rate levied, the Corporation had got themselves into considerable financial difficulties, and were unable without financial assistance to provide for their current expenditure. They had at this time unexhausted borrowing powers which (upon the sanction of the Local Government Board being obtained) would, if exercised, have to some extent enabled them to recoup their expenditure upon capital account, and in December, 1905, they applied for sanction to borrow moneys in respect of certain works. It is only fair to the Corporation to say that the sanction which was ultimately given in respect of the greater part of their application was not so given until April 1, 1908, and this delay undoubtedly added to their embarrassment, and tended to prolong the period during which they sought assistance. In November, 1905, the Corporation applied for an overdraft to the London & County Bank, and after some negotiations an overdraft was granted to them to the extent of £120,000, subsequently increased to £200,000. From the time when the overdraft was granted until shortly before the commencement of the action the accounts were almost continuously overdrawn. At the time the Corporation obtained the overdraft they had unexhausted borrowing powers, and he would assume that these were in excess of the overdraft, though the evidence was somewhat meagre on the point. The Corporation appear to have considered, and they certainly acted as though they were entitled to use, moneys borrowed under specific powers, not merely for the specific purposes for which the powers were bestowed, but for any purpose to which any funds of the Corporation could lawfully be applied, so long as they kept proper accounts of the expenditure. He thought the correspondence and applications to the bank showed that the Corporation intended so to apply the bank's advances from the first; and, in fact, the overdraft was allowed on all the accounts and a general balance struck daily. In his opinion this view of the position of the Corporation was erroneous. If they raised moneys under a borrowing power they were bound to apply the moneys so raised for the specific objects indicated by the statute. He thought that upon this ground the obtaining of the overdraft was ultra vires. Whether an overdraft extended over several years for substantially the whole amount of the authorised loan could be justified as a temporary loan within the meaning of the decisions he need not decide; but in his opinion the question was at least doubtful. Upon the point whether they were entitled to borrow money by way of overdraft for general expenditure, at all events, except under special circumstances, he also reserved his decision. The impropriety of municipal corporations incurring large expenditure on capital account in anticipation of sanction for loans not yet obtained was well illustrated in the present case, where the Corporation failed to obtain sanction for a loan in respect of an expenditure of over £10,000 on electricity account, with the result that they were driven to make a levy for the amount—in his opinion an illegal levy, inasmuch as the proceeds were applied in payment of liabilities incurred more than six months before the levy of the rate. The bank having agreed terms, he refrained from discussing what, upon the evidence, their position would have been in respect of their advances. On March 31, 1908, the general account of the Corporation with the bank was overdrawn to the extent of some £38,000, after deducting the amount due to the consolidated loans fund, but which had from time to time been paid into the account in reduction of the overdraft, in accordance with an arrangement with the bank. In his opinion the application of the amounts due to the consolidated loan fund in reduction of the overdraft was illegal.

At the trial application was made for leave to plead the Public Authorities Protection Act, 1893, and the Trustee Relief Act, 1888. In the course of the trial he gave such leave, and the matter proceeded upon that footing. Counsel for the Attorney-General having refrained from asking for relief against the defendant Patterson personally, the Trustee Relief Act could have no application. The question of the applicability of the Public Authorities Protection Act, 1893, was not fully argued. In his opinion it would apply in favour of the Corporation and the borough treasurer in respect of acts completed more than six months before the action. The overdraft, however, from the bank and repayment out of moneys due to the consolidated loans fund continued up to a period within six months before the commencement of the action, and he thought the plaintiff was entitled to declarations in respect of such continuing illegality, although the plaintiff was not entitled to all the relief claimed. Having regard to the time at which the application to amend was made, he thought this should make no difference as to the incidence of the costs of the action. He proposed to declare (1) that the overdraft obtained from the bank for general purposes in respect of borrowing powers granted for specific purposes was ultra vires and illegal; (2) that the application of money due to the consolidated loan fund in repayment of such overdraft was altra vires and illegal; (3) that the borrowing of money from the bank for the purpose of the electricity accounts, otherwise than in the exercise of borrowing powers with the sanction of the Local Government Board, was ultra vires and illegal. The defendant Corporation and the defendant Patterson must pay the costs of the action.

Mr. DANCKWERTS (for the Corporation): Your lordship promised to say something about the sanction of the Local Government Board being held back. If we get the sanction it will put us straight and we shall be able to proceed.

His LORDSHIP said he could not make any statement as to that.

Mr. DANCKWERTS asked his lordship for time, so that the Corporation could put themselves straight. He suggested until March 31, so that they should not be presumed to intentionally break the declaration that your lordship has made.

His LORDSHIP said he did not think there were any means by which the declarations he had made could be enforced. He had not granted an injunction. He thought his judgment had no further operation than that it made it res judicata between the Attorney-General and the Corporation.

J. & H. Gravener v. J. M. Smith.

In the Shoreditch (London) County Court on Tuesday, before his Honour Judge Smyly, K.C., plaintiffs sued defendant to recover £14. 0s. 3d. for arc lamps and carbons supplied.

Evidence for plaintiffs was to the effect that in September, 1909, they negotiated at their Manchester branch with defendant to supply arc lamps to the value of £10 and carbons to the balance of the debt. It was agreed they were on sale or return for 14 days. From that time they heard nothing until payment was pressed for, when there was a query as to the current taken by the lamps, and that was put right.

Defendant said the lamps were sent on approval to be tried. He found they burned far too much electric current and decided to reject them, but offered to pay for the carbons as they were all right. Plaintiffs agreed to pay the carriage both ways if he did not like the lamps.

Judge SMYLY: How long were the lamps used?—Defendant: About three months.

Judge SMYLY: But surely you are not entitled to use electric fittings for three months and then reject them?—Defendant: My agreement was that I should have them a reasonable time for testing, but no definite period was fixed.

Judge SMYLY: But can you call three months a reasonable time? it seems very unreasonable to me. Defendant: They had to be tested, and I had to use different carbons to do that, which could not be done in a few days. My refusal of them was because I found out afterwards why there was so much current used and that there had been misrepresentation. Then again, I object to being brought to London from Bolton when the affair was arranged in Manchester.

Judge SMYLY: Payment would be in Manchester, so I have no jurisdiction.

Mr. WHITE (for plaintiffs): Defendant knew he was dealing with a London firm.

Defendant: No, I did not; I had no knowledge of a London office.

Judge SMYLY: The contract was made in Manchester, and it is a great hardship bringing a man up all this way.

Mr. WHITE: Anyway he admits his liability for the carbons.

Judge SMYLY: But that is not the point. It is a great shame to launch such actions in London, as it often happens that a person who has got a thoroughly good defence has no money to fight the action by way of coming to town, and judgment is obtained against him illegitimately. I decide the Court has no jurisdiction, and the action is dismissed.

Defendant: Can I have my costs of coming to London?

Judge SMYLY: Yes, most certainly.

Overhead Telephone Wires.

Last week the Railway and Canal Commission heard the appeal of Croydon Corporation against the decision of Judge Harington, allowing the Postmaster-General to erect telephone poles for overhead wires in roads in Croydon, Norbury, &c. The facts were reported in THE ELECTRICIAN for June 24 (p. 447), but additional witnesses were called for the Postmaster-General, and, in the result, the chairman of the Commissioners (Mr. Justice A. L. Lawrence) delivered judgment upholding Judge Harington's award.

PARLIAMENTARY INTELLIGENCE.

Royal Assent.—On July 26 Royal Assent was read to the following new Acts of Parliament, in addition to those mentioned in our last issue: Dunfermline and District Tramways (Extensions) Order Confirmation, Wemyss Tramways (Extensions) Order Confirmation, Electric Lighting Orders Confirmation (No. 3) Bishop's Stortford, Harlow and Epping Gas and Electricity, Yorkshire Electric Power, Reading and District Electric Supply and Belfast Corporation (Tramways). The London County Council (Tramways and Improvements) Act received the Royal Assent on Wednesday last.

Birmingham Extension Bill.—The Select Committee of the House of Commons, presided over by Mr. D. A. Thomas, which has been considering the bill to confirm a provisional order made by the L.G. Board for extending the boundaries of the City of Birmingham, decided on Wednesday to confirm the order, except so far as it relates to the separation of Handsworth from the West Bromwich Union. The added area includes Aston, Erdington, Yardley, &c.

Customs Duties.—A recently issued supplement to the Australian Customs Tariff Guide states that it has been decided that automatic arc lamp couplings (not integral parts of the lamps) are subject to import duty of 17½ per cent. (British goods 10 per cent.), and switch cases, consisting of c.i. case enclosing switches and fuses with or without ammeters, voltmeters, &c., 20 per cent. (British or otherwise), bronze statuettes with conduit passing through for electric wires or gas 25 per cent. (British 20 per cent.). Magneto parts (imported in sets) are duty free.

MUNICIPAL, FOREIGN & GENERAL NOTES.

APPOINTMENTS VACANT AND FILLED.

The Council of the University of Birmingham invite applications for the appointment of assistant lecturer and demonstrator in electrical engineering. Candidates must be graduates, and must have had experience in the test room of first-class electrical engineering firm. Stipend £150 per annum. Applications to the secretary, Mr. Geo. H. Morley, by Sept. 17. See an advertisement.

The governing body of the Northampton Polytechnic Institute London, invite early applications for the appointments of senior assistant in the electrical engineering department, to take charge of new electric generating station (salary 45s. per week); junior assistant in electrical engineering department, chiefly to take charge of producer plant (28s. per week); second lecture assistant in electrical engineering department (£80 per annum); and assistant lecturer and demonstrator in the mechanical engineering department (£120 per annum).

Applications will be received until Sept. 10 for appointment to the Henry Overton Wills Chair of Physics at Bristol University. Salary £600 per annum. Particulars from the Registrar.

A lecturer in mechanical engineering is required at Blackburn Municipal Technical School. Salary £120 to £140. Forms from the Director of Education. Applications by Aug. 13.

A Canadian publishing house advertise for an experienced editor for an electrical journal.

An instructor for engineering workshop classes is required at Guildford Technical Institute. Applications by Aug. 10.

Assistant Examinerships in the Patent Office.—Applications to enter for the forthcoming examination to qualify for appointments as assistant examiners (20-25) must be sent in by Sept. 1. Forms and particulars from the Secretary, Civil Service Commission, Burlington-gardens, London, W

EDUCATIONAL NOTICES.

University of London, University College.—The 1910-11 session begins on Monday, Oct. 3. Full particulars from the secretary, Mr. Walter W. Seton, M.A. Intending students should communicate with the Provost not later than Sept. 20.

University of Liverpool.—The session 1910-11 commences on Tuesday, Oct. 4. The courses of study in the faculty of engineering leading to the ordinary degree of Bachelor of Engineering extend over at least three years, and are so arranged as to afford a general scientific training for those who intend, with or without graduating, to become engineers, naval architects or architects and surveyors. Students who do not proceed to a University degree may take a course of not less than two years, leading to a certificate in engineering. The honours schools enable students to specialise in some branch of the profession, and opportunities are afforded for post graduate work and research. Prospectus of the faculty can be obtained from the Registrar, Mr. P. Hebblethwaite, M.A.

University of Glasgow.—The next session will commence on Oct. 17. Prospectus of course in engineering and syllabus may be obtained from the Assistant Clerk, Matriculation Office, The University, Glasgow.

City and Guilds of London Institute.—The entrance examinations of the City and Guilds Central Technical College, Exhibition-road, S.W., and the City and Guilds Technical College, Finsbury, E.C., are held in September, and the sessions commence in October.

Both institutions provide courses of instruction in engineering, chemistry, mechanics and mathematics, &c. Particulars of entrance examinations, scholarships and courses of study may be obtained from the respective colleges or at the head offices of the Institute, Gresham College, Basinghall-street, London, E.C. The Central Technical College is intended for higher technical instruction for day students not under 16 years of age, preparing to become civil, mechanical or electrical engineers, chemical or other manufacturers and teachers. The college is a school of the University of London, and forms the engineering section of the Imperial College of Science. The courses of the study for the associateship of the Institute cover a period of three years.

The City and Guilds Technical College at Finsbury (London, E.C.) is designed for day students preparing to enter engineering and chemical industries and for those who have already served an apprenticeship and also for evening students. The day courses in mechanical or electrical engineering cover two years and those in chemistry three years.

Armstrong College, Newcastle-on-Tyne.—The next session commences on Sept. 26. The matriculation examination takes place on Sept. 20-23. There are full courses of instruction in mechanical, marine, civil and electrical engineering, naval architecture, mining, metallurgy, agriculture, pure science, arts and letters. Particulars from the secretary, Mr. F. H. Pruen, M.A., Armstrong College, Newcastle-on-Tyne.

East London College (University of London).—The new session commences Sept. 26. There are courses in civil, mechanical and electrical engineering. Fees, 10 guineas per session. Courses in the evening are also held at moderate fees. Calendar may be obtained free from the Registrar or of the Principal (Mr. J. L. S. Hatton, M.A.). The college is situated in the Mile End-road, near G.E. and L.T. & S. stations.

BRITISH NOTES.

Accrington.—The Electricity committee have drawn up terms for the supply of current to Haslingden Corpn., and it is proposed to apply to the Board of Trade for an order permitting the Accrington Corpn. to supply current in bulk to Haslingden.

The committee have decided to instal a storage battery, the cost to be defrayed out of revenue.

A permanent showroom is to be opened for exhibiting electric motors, fittings, &c.

Bath.—The City Council has decided to invite tenders for the lighting of the Long Acre Technical Institute. The electrical engineer (Mr. F. Teague) is to prepare specifications.

Brighouse.—At a meeting of the Council last week a report was presented in reference to an interview between representatives of the Corporation and the officials of the Yorkshire Electric Power Co.

Negotiations had been in progress for the supply of electric energy for power at a cheaper rate than hitherto. Under an agreement the Corporation now takes electricity in bulk from the power company at a maximum charge of 1½d. per unit. The company made the following offer: "For supply to power users connected to the Corporation's existing d.c. system (the amount to be deemed at 67 H.P.), a flat rate of ¾d. per unit; for units used for balancing, ¾d. per unit; for all other current, 1½d. per unit. If the total charge ascertained as above exceeds the charge of the sliding scale in the existing agreement, the account will be rendered on the lower basis." These terms were accepted, provided they apply to all energy taken by the Corporation from the company on the d.c. system up to a maximum of 250 kw. It has also been decided to supply current for power at 1d. per unit to any consumer in the town with a minimum consumption of 5,000 units per quarter. The Power Co. are to be allowed to lay mains through Brighouse, partly underground and partly overhead, for supplying in Sowerby Bridge.

Chelmsford.—Tenders for lighting the public lamps for three or five years from April 1 next have been received from the Electric Supply Corpn. (who carry out the public lighting at present), and the Chelmsford Gas, Light & Coke Co.

The former company state that they have decided to substitute metal filament lamps for Nernst lamps. They offered to light the north and south wards with 21 flame arc lamps at £25. 5s. per lamp per annum with 23 incandescents at street corners of 200 c.p. and with 280 of 100 c.p. at 3 guineas per lamp per annum, and also to provide the Springfield ward (now lighted by gas) with 33 100 c.p. incandescents at 3 guineas per lamp per annum. The gas company have submitted three tenders, the last one stating they are prepared to supply all the necessary lamp columns, lanterns and other apparatus for lighting the whole of the borough for £3. 4s. 6d. per lamp per annum; the lighting power of the single-burner lamps to be of 125 c.p., and of the double-burner lamps at street corners 160 c.p. In place of the flame arc lamps they would agree to erect, light, and maintain 21 incandescentgas "arc" lamps of 1,200 c.p. for £18 per lamp per annum.

The tenders have been referred to a sub-committee.

Croydon.—The borough electrical engineer (Mr. A. C. Cramb) reports that the regulations of the Home Office as to factories will necessitate an estimated expenditure at the electricity station of £1,176.

Delivery of Telegrams by Telephone.—The Secretary of the General Post Office has issued the following letter (dated July 26) to subscribers to the Post Office telephone system:—

The Postmaster-General is desirous of substituting delivery of telegrams by telephone for delivery by boy messenger, and this method is now being adopted experimentally in the case of telephone subscribers whose telegrams are ordinarily sent to them from the ——— Post Office. Delivery is quicker by telephone than by messenger and, where attention cannot be obtained at once by telephone, the message is sent out in the usual way by hand. In every case of telephone delivery the written telegram is forwarded by post. Unless you notify to the contrary, the Postmaster-General will assume that he will receive your co-operation in the experiment.

Any communication with regard to this matter should be addressed to the General Manager, Post Office London Telephone Service, General Post Office (South), E.C.

Digitized by Google

Eccles.—Sanction has been received by the Council to a loan of £3,234 for generating plant and mains extensions.

Exhibition.—An international exhibition of iron and metal wares and machinery will be held at Budapest (Hungary) in May next.

Fleetwood.—An inquiry was held here on Thursday into the application of the Council to borrow £4,100 for extensions of the electricity undertaking.

Frome.—The Council last week sealed the agreement to transfer their electricity undertaking to Edmundson's Electricity Corpn. The Council agree to pay the company £8,278, balance of the capital amount due to the company, and to take a supply of electricity for lighting the streets until April 6, 1928, the prices to be revised next year, and every subsequent five years. The company agree to repay in half-yearly instalments the interest and sinking fund or instalments on loans (amounting to £43,278) which the Council have incurred. The company may be required by arbitration to sell the undertaking to the Council, the valuation of lands, buildings, and works not to exceed £70,000.

Glasgow.—On Friday the Electricity committee approved the accounts for the year ended May 31. No change is to be made in the charges for electric current during the present year.

The Electricity committee recommend the following rates of depreciation on the various items in the capital account for 1909-10: Land and buildings, 1 per cent.; machinery, plant, instruments, transformers, &c., 3½; accumulators, 5; mains and cables, 2; and meters and indicators, 4. On the basis of the rates for 1908-09 the depreciation for the year 1909-10 would be £57,930. 18s. 4d., and on the basis proposed the amount will be £43,474. 18s. 1d.

Hammersmith.—The New Olympia Co. have decided to generate their own current for the purpose of demonstrations of country house lighting at the electrical exhibition to be held at Olympia in September, 1911, and will pay Hammersmith Council a royalty of ¾d. per unit, as the company are under an agreement to take all current required from the Council's works at a low price.

Holborn (London).—The Council have rejected by 15 votes to 6 a recommendation of the Works and General Purposes committee to enter into a 10 years' contract with the Gas Light & Coke Co. for street lighting with inverted burners.

The matter is to be brought up again in October, and in the meantime a tender for electric lighting will be obtained. Councillor H. Foulds was the leading opponent of the committee's recommendation.

The Borough Surveyor reported having prepared an estimate of the cost of alternative systems of electric lighting applied to High Holborn and New Oxford-street only as follows: By existing lanterns adapted, 18,000 c.p., first cost £75, annual cost £483; by new standards for arc lighting, 40,000 c.p., first cost £800, annual cost £680; by new suspended lamps for ditto, across street, 40,000 c.p., first cost £290, annual cost £680; by flame arc lighting, 120,000 c.p., first cost £1,000, annual cost, £680. The committee considered that the adoption of either electric light or high-pressure gas would involve considerable expense and the disturbance of the pavements, and, therefore, they did not recommend either.

Institute of Chemistry.—The pass list of the July examinations has been issued and shows that:—

59 candidates presented themselves. 17 passed the intermediate examination: D. L. Allan, S. W. Bridge, G. M. Carruthers, D. S. Dawson, B.Sc., F. E. Day, B.Sc., G. J. Eastburn, W. J. S. Eastburn, H. D. Elkington, Maud Gazdar, B.Sc., D. Hamilton, G. Hamilton, W. P. Harmsworth, W. Jewell, R. W. Pope, S. P. Schotz, J. Sorley, J. C. White. In the final examination 1 candidate passed in mineral chemistry: C. S. Grace, B.Sc.,; 1 in metallurgical chemistry: W. A. Riley; 10 in organic chemistry: F. L. Bassett, B.Sc., F. Challenger, B.Sc., F. A. F. Crawford, B.A., E. G. Davis, W. Dickson, J. R. Nicholls, G. C. Petrie, E. F. Pollock, T. Schwarz, T. A. Simmons, B.Sc.; and 8 in the chemistry of food and drugs, &c.: H. M. Harvey, D. Henville, F. E. Laughton, H. R. Lyell, W. M. Paulley, B.A., P. L. J. Smith, M.A., R. W. Warrick. 1 passed a final (A.I.C.) examination in general chemistry: J. B. Solomon, A. R.S.M., A.R.C.S.; 1 passed a special examination for the fellowship: Colin C. Frye; and 1 passed in the chemistry of food and drugs, &c.: G. W. Monier-Williams, B.A., Ph.D., F.I.C.

Leicester.—An inquiry was held on Friday last into the Council's application for sanction to borrow £19,190 for extensions of the generating plant at the tramway power station.

It was stated that the loan was required to meet the increasing demand for power. From September, 1908, to the end of the year, 63,192 units were supplied for power from the station; in 1909, 434,262 units; in the half-year ended June last, 609,285 units; and the engineer's estimate for the whole of the present year is 1,250,000 units. In view of the constantly increasing demand the proposed extension was considered to be the minimum the Corporation could safely ask for.

The electrical engineer (Mr. T. R. Smith), who gave evidence in support of the application, was of opinion that the extension would meet demands for the ensuing 18 months or two years.

Listowel (Ireland).—Messrs. Wilkins & Burden, of Dublin, are asking the Council's consent to their electricity supply scheme for the district. It was decided to take no action.

Marylebone (London).—An agreement has been entered into for the supply of electricity to the London Polytechnic's new premises in Regent-street under a restricted hour basis. The electricity department has arranged with the Metropolitan Railway Co. for lighting with electricity the gas lamps belonging to the company over the "blow-holes" of the railway in the Marylebone-road.

New Atlantic Cable.—Reuter's Agency announced that the Telegraph Construction & Maintenance Co.'s s.s. "Telconia" arrived at St. Johns, Newfoundland, on July 31, to lay the shore end of the Western Union Telegraph Co.'s new cable at Bay Roberts. Another cable ship (belonging to the T. C. & M. Co.) is to follow shortly with the deep sea section.

Personal.—We are informed that Mr. George G. L. Preece, A.M.I.E.E., M.Inst.M.E., for 15 years with W. T. Glover & Co., and for the last few years acting as their technical and special outside cable expert, has joined the firm of Bruce Peebles & Co.

Mr. Jas. R. Wilkinson, son of Mr. Geo. Wilkinson, borough electrical engineer, Harrogate, has finished his course at University College, London, by obtaining the College diploma in engineering, "with distinction," and winning three prizes. He has also obtained the London degree of B.Sc. in the second class honours division. During the college course Mr. Wilkinson has been a member of the Officers' Training Corps and has passed the examinations qualifying for a commission in the special Army Reserve of Officers. He is to be gazetted, and afterwards joins his regiment for four months' military training. At the expiration of this period he has been appointed to take a three years' course of practical engineering in the Royal Arsenal at Woolwich.

Presentation.—On the occasion of his marriage, Mr. W. A. Walker, electrical engineer at Kettering, has been presented by the chief officers of the Council with a Sheraton timepiece.

Preston.—In connection with the express parcel delivery system on the tramways, which was introduced at the beginning of the year, between 3,000 and 4,000 parcels have been carried at a minimum charge of 2d. per 14 lb. It is now proposed to reduce the minimum charge to 1d. for 7 lb.

Provisional Order Revocation.—The Board of Trade have revoked the Market Harborough Electric Lighting Order, 1906, as from July 20.

Railway Accidents.—The report to the Board of Trade by Mr. W. F Marwood, Assistant Secretary (Railway Department) on the accidents on the railways of the United Kingdom in 1909 states that the total route length of the railways was 23,264 miles.

In Class I. (train accidents) two occurred on electrically-worked lines, one being the collision at Marsh-lane Junction on the Lancashire & Yorkshire Railway on Jan. 21, and the other the collision of an empty train with the buffer stops at Ealing Broadway station on Nov. 18. In the latter the motorman and one of the conductors were killed.

In Class II. none of the accidents are specially described as electrical.

In Class III. it is mentioned that, although these accidents are not as a rule attributable to railway working, an exception must be made in the case of accidents caused by contact with the live rails and wires of electrified railways, which are distinctly railway accidents, though not caused by the movement of vehicles. To this cause must be set down the death of 1 servant and injury to 9 others in 1909. In 1908 1 servant was killed and 14 were injured in this way, in 1907 1 killed and 13 injured, in 1906 1 killed and 10 injured, in 1905 1 killed and 13 injured, and in 1904 1 killed and 9 injured. Precautions against the recurrence of such accidents have been taken by covering the live rail at exposed places, improving fencing and posting warnings. Accidents of this class have become less frequent than they were when electrical working was introduced.

St. Paul's Bridge.—At their meeting on Thursday last, the City of London Court of Common Council discussed a communication from London County Council in reference to the proposed additional bridge over the Thames between Southwark and the City.

The letter stated that the Improvements committee of the County Council were prepared to recommend the Council to make a contribution limited to one-half of the net cost of the proposed widening of St. Paul's Churchyard, this contribution being limited to £300,000, and subject to the condition that the Council shall be satisfied as to the details of the scheme in all respects, and in particular as to the adequacy of the southern approach to the bridge, the whole arrangement to be further subject to the Council being afforded such facilities as it may desire for constructing tramways on the new bridge and approaches, it being understood that the Council shall be under no obligation to construct such tramways, or, if constructed, to extend them to the north of Cheapside, so as to link up with the existing tramways in Aldersgate-street.

Mr. THOMAS said the Bridge House Estates committee would report after the vacation, and the court might then decide to proceed with the applications to Parliament without the concurrence of London County Council.

Sewage Pumping by Electricity.—An automatic electric pumping station owned by Norwich Corporation was opened at Eaton Village last week. The installation comprises Rees Roturbo centrifugal

Digitized by Google

pumps and electrical plant supplied by Messrs. Laurence, Scott & Co. A float in the sewage chamber automatically turns the switch to start or stop the pumping plant. The plant was erected under the supervision of the city engineer (Mr. A. E. Collins) and his deputy.

School Ventilation.—A "Daily Express" correspondent states that electric pumps for supplying filtered air are being installed in new elementary and grammar schools in Vienna, as the dust in the air has been found to be the chief cause of consumption.

Southgate.—The agreement with the North Metropolitan Electric Power Supply Co. for the supply of electricity has been sealed. The company must lay the mains within 18 months in a number of the leading thoroughfares, but it is anticipated that supply will be available January next.

Stoke-on-Trent.—The Council on Thursday last decided, on the recommendation of the Electricity committee, to give three months' notice to terminate the engagements of the present electrical engineers of the electricity works at Burslem, Longton and Stoke (which towns, with Hanley, are now included in the new federated borough of Stoke), an amendment, moved by Ald. Malkin, that their services be retained until the chief engineer (Mr. C. H. Yeaman, hitherto of Hanley) had obtained a thorough knowledge of all the undertakings having been defeated.

West Bromwich.—The Electricity committee have declined an offer of the Shropshire, Worcestershire and Staffordshire Electric Power Co. to supply electricity in bulk to the Corporation electricity department, charges being considered too high.

West Ham.—Application is to be made to the L.G. Board for sanction to a loan of £1,500 for water-cooling plant. This loan is to be added to an application for £52,000 already before the Board.

The Borough Treasurer reported at the last meeting of the Council having received a letter from the borough electrical engineer (Mr. H. H. Couzens) as to proceeding with certain works included in the application for loan sanction, and stating that the most important matters appeared to be the Silvertown and Stratford extensions. The Borough Treasurer asked for instructions, and it was decided that a deputation from the Council, headed by the Mayor, should interview the President of the L.G. Board with a view to obtaining the necessary sanction.

Mr. Couzens has reported on the question of purchasing meters out of revenue, and has given a comparison between the cost to be defrayed each year if purchase is made direct from revenue, or on the basis of five years' loan. The figures show that while the average increase over the five years' period by paying direct to revenue on this basis is 30 per cent., the increase for the earlier years is much more, amounting in the first year to 300 per cent.

It was decided that in future the cost of meters be charged direct to revenue.

The chairman of the Electricity committee and Mr. Couzens were empowered to accept the most favourable tender for ash conveyers at the generating station. The estimated cost is £500.

In regard to a bulk supply to the Port of London Authority heads of agreement have been arranged.

It has been decided to support the Municipal Electrical Association in their efforts to promote a bill to amend the Electric Lighting (Amendment) Act, 1909, so as to secure powers to local authorities to supply and fix fittings and wires on consumers' premises, and the inclusion of the stand-by clause and the clause dealing with "supply by unauthorised undertakers," which were struck out of the act.

The borough surveyor has been instructed to obtain prices for 15 fire alarms.

Weymouth.—The L.G. Board have sanctioned a loan of £150 for tools, &c., at the electricity works.

Will.—The will of the late Major Philip Cardew, of Messrs. Preece & Cardew, and a director of the L.B. & S.C. Railway, who died on May 17 last, has been proved of the gross value of £30,332; net personalty £10,925.

Wireless Telegraph Notes.—It is announced that the traffic over the Marconi Wireless service in connection with the Crippen affair has reached nearly 100,000 words.

The interchange of duties between the signal and the wireless telegraph branches of the British nautical service has, owing to the fact that the telegraph branch cannot reach its full strength for some time, occupied the attention of the Admiralty authorities, who have directed the following steps to be taken to expedite the wireless organisation on board ship to the full extent possible with the number and grades of ratings available:—

1. Every effort is to be made to train young signalmen to take a share of the work in the wireless room in conformity with the intention of the Admiralty letter issued July, 1908, and, so far as is practicable, ordinary deck hands are to be utilised in subsidiary wireless telegraphy duties. With daily practice and careful training it should be possible to make in any case a proportion of the signal staff competent to take their turn in the wireless cabinet.

2. Commanding officers are also to take steps to secure, if possible, further interchange of duties between the wireless and signal staffs by employing wireless ratings off watch for two or three hours a day on the bridge. It is considered that the ordinary day's work of wireless ratings need not necessarily be limited to a maximum of six hours in the wireless room, and that a turn of employment on deck would be of advantage.

3. In order to afford further relief to the signal and wireless staff, all signalling is to be reduced to a minimum, compatible with actual service requirements.

In another column of this issue, an Act is set out which recently came into effect in America, providing for the compulsory equipment of wireless telegraph apparatus on board certain vessels entering or leaving United States ports. A similar measure is before the British Parliament, and is being discussed in shipping circles. At a recent meeting of the North of England steamship owners a special committee was appointed to draft objections to this measure.

The success which has attended trials of wireless telegraphy on one of the Brazilian railways (the Madeira-Mamoré Railway) has led to the Minister of Public Works being authorised to receive proposals for the installation of three radio telegraphic stations (Marconi system) in the Province of Acre, for which there may be a public call for tenders.

We recently reported that the use of wireless telegraphy by the fishing fleet which centres at Grimsby had not proved of the service which was anticipated. The owners of a German fleet of fishing boats appear to have been more successful, and have employed wireless communications as a means of consolidating their fleet and systematising the catch, at the same time regulating their supplies to the markets in such manner as to make them more regular and by avoiding gluts of greater value.

It was to be expected that the most would be made of the opportunities afforded by wireless telegraphy on board the ocean liners by those who are blessed with a large share of this world's wealth. It is reported that a number of ladies travelling on the liners have utilised these facilities for "shopping by wireless." While the money lasts there are potentialities here.

Workhouse Lighting.—At the meeting of Tipperary Guardians last week the chairman referred to a motion standing in his name in reference to the borrowing of £2,280 for lighting and heating the workhouse, which motion, he said, fell through on account of his unavoidable absence.

He saw by the press reports that he was supposed to be under censure for handing in such a motion, but a majority of the board had signed a form in favour of borrowing the amount. Mr. Lawless (electrical engineer) had estimated that the total yearly cost of repaying the principal and interest on the loan, depreciation and cost of fuel and wages would be £405. 10s., whereas the lowest figure to which fuel and gas could be brought was £682, so that there was a balance of £277 odd in favour of electricity.

The chairman subsequently gave fresh notice of the motion.

Wrexham.—The Council have applied for sanction to a loan of £3,345 for extensions of the electricity works.

COLONIAL AND FOREIGN NOTES.

Australasia.—The "Age" (Melbourne) states that Melbourne Corporation intend to raise a loan of £300,000 for public works, including £86,000 for extensions of the electricity supply undertaking.

For the supply of water from the Hawkesbury river to Hawkesbury Agricultural College electric pumping plant has recently been installed for the N.S.W. Public Works Department. The plant includes a Sentinel engine coupled to a British Westinghouse dynamo, which supplies current for operating "Bon Accord" centrifugal pumps. The water is pumped nearly 4 miles, and the current is transmitted that distance from the generator at the college to the motors for operating the pumps at the river side. The supply of water thus delivered averages 9,700 gallons per hour.

The "Australian Mining and Engineering Review" says Mr. G. H. Lofts has prepared plans in connection with the projected electric lighting and power supply in Ulverstone (Tasmania), and tenders will shortly be invited for supply of plant, including two Babcock & Wilcox boilers with superheaters, 80 B.H.P. non-condensing engine direct-coupled to a 50 kw. 440-500 volt dynamo, two balancers and boosters, &c. A 250 cell storage battery is also to be installed, and about 36,500 yds. of mains and cables will be required.

Chillagoe (Queensland) Council have been approached on the subject of lighting the streets electrically.

Euroa (V.) Shire Council have appointed a sub-committee to report on the practicability of establishing municipal electricity works.

Austria-Hungary.—It is stated that Budapest Municipality have not been able to come to an agreement for taking over the remainder of the concession of the two great electric supply companies of that city, and are consequently considering a project for the erection of a third electric power station to be carried on under their own control.

France.—Consul C. A. Payton (Calais) writes that the harbour authorities are arranging a submarine bell at the extremity of the east pier at Calais, so that the mail boats, being fitted with telephonic

Digitized by Google

receivers, will be able to direct their course to the entrance of the harbour.

From Boulogne Vice-Consul Farmer reports that there is a "Renard" road service between Wimereux and Audresselles.

Vice Consul Walker (Lille) states that his attention has been drawn to the difficulties experienced at the customs since April 1 by importers of British machinery, when the new tariff came into force. To avoid trouble and possible fines it should be observed that on declaration at customs a plan or drawing of the machine must be produced. The weight of the machine must be given very exactly, and extra change pieces should be packed apart from the machine, and declared separately.

Holland.—The communal authorities of Groenlo have granted a concession for the construction of a tramway from Boreulo to Winterswijk, thence to the German frontier.

Nymegen communal authorities have decided to take over the working of the steam tramways and to convert them to electric traction at a cost of about £80,000.

Amsterdam Municipality are purchasing some new machinery for their electric power works and are about to enlarge the electric tramcar depots.

A project for the establishment of an electric power station for the towns of Deventer and Zwolle has been adopted by Deventer Municipal Council.

Italy.—The Italian State Railways Department, have prepared a project for the electrification of about 553 miles of the State Railways, and the erection and equipment of hydro-electric works near the river Wuocken.

Japanese Customs Duties.—A publication is issued by the Tariff Commission on the effect which the proposed Japanese Tariff (which comes into force July 1, 1911) will have upon British Trade.

It is stated that taking the 16 leading groups of commodities exported to Japan (which accounts for 90 per cent. of the trade) the increases since 1895 have been: United Kingdom £4,750,000, or 116 per cent.; Germany £3,000,000, or 300 per cent.; United States £3,000,000, or 1,400 per cent. German progress in Japan is especially marked in iron and steel and chemicals, and the United States has advanced mainly in iron and steel and machinery. The United States has the predominant share of Japanese import trade in electrical machinery; Germany predominates in locomotives and iron bars; and Gt. Britain in ships and in textile machinery.

According to Japanese trade returns the average duty collected on dutiable goods from all countries in 1909 was 16 per cent. An examination of items representing over 85 per cent. of these imports shows that if the new tariff comes into force without amendment the average rate of duty on dutiable goods from all countries will be increased to 23 per cent., or nearly one-half. On United Kingdom imports alone the average rate will be increased from 10½ to 17½ per cent., or two-thirds. The dutiable imports from the United Kingdom are about one-third of the total from all countries. The United Kingdom, however, sends about one-half of the articles which have to bear the principal increases of duty. Thus the amount of imports from the United Kingdom likely to be excluded under the new tariff is estimated at between one-third and one-half of the total of 20 million yen.

Amongst the proposed new duties are the following (present duties shown in parentheses):—Incandescent lamp filaments, 20 per cent. (30 per cent.); electric batteries (other than accumulators and dry batteries), 25 per cent. (20 per cent.); steam turbines, 20 per cent. (15 per cent.); dynamos combined with steam turbines, 20 per cent. (15 per cent.); motive machinery (n.o.p.), 20 per cent. (15 per cent.); gas engines 26·4 per cent. (15 per cent.); motors 28·4 per cent. (15 per cent.).

Statistics appended to the publication show that amongst the imports to Japan in 1909 from the U.K. and from all other countries were the following:—Submarine and underground cables, British, £20,000, other countries, £37,000; insulated wire £109,000 and £155,000; parts of electric cars, £36,000 and £115,000; steam engines £59,000 and £72,000; gas, oil and hot air engines £30,000 and £39,000; steam turbines £4,000 and £24,000; electric machinery £84,000 and £306,000; steam boilers £86,000 and £93,000.

Russia.—Mr. C. S. Smith, British Consul-General at Odessa, has written an interesting note on the subject of the advantages and disadvantages of exhibiting machinery at Russian exhibitions. The general trend of Mr. Smith's remarks go to show that the game is not worth the candle. The expenses of exhibiting in Russia appear to be very heavy without showing any adequate return.

U.S. Compulsory Wireless Act.—Following is a copy of the Compulsory Wireless Act recently passed by Congress (and formally approved June 24, 1910), and which has now become law in the United States:—

Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled, That from and after July 1, 1911, it shall be unlawful for any ocean-going steamer of the United States, or of any foreign country, carrying passengers and carrying 50 or more persons, including passengers and crew, to leave or attempt to leave any port of the United States unless such steamer shall be equipped with an efficient apparatus for radio communication, in good working order, in charge of a person skilled in the use of such apparatus, which apparatus shall be capable of transmitting and receiving messages over a distance of at least 100 miles, night or day: Provided, that provisions of this Act shall not apply to steamers plying only between ports less than 200 miles apart.

(2). That for the purpose of this Act apparatus for radio-communication shall not be deemed to be efficient unless the company installing it shall contract in writing to exchange, and shall, in fact, exchange, as far as may be physically practicable, to be determined by the master of the vessel, messages with shore or ship stations using other systems of radio-communication.

(3). That the master or other person being in charge of any such vessel which leaves or attempts to leave any port of the United States in violation of any of the provisions of this Act shall, upon conviction, be fined in a sum not more than $5,000, and any such fine shall be a lien upon such vessel, and such vessel may be libeled thereafter in any district of the United States within the jurisdiction of which such vessel shall arrive or depart, and the leaving or attempting to leave each and every port of the United States shall constitute a separate offence.

(4). That the Secretary of Commerce and Labour shall make such regulations as may be necessary to secure the proper execution of this Act by collectors of Customs and other officers of the Government.

ELECTRICITY SUPPLY AND TRAMWAY ACCOUNTS.

Aberdeen.—The accounts of the tramways department for the year ended May 31 last show capital expenditure £353,078, against which £37,250 has been appropriated for depreciation, £28,399 contributed to sinking fund, £103,601 placed to renewal account, while the amount paid out of revenue for preliminary and Parliamentary expenses and written off property is £7,658.

Revenue was £71,121 (decrease £559), including traffic receipts £70,078, of which £64,688 was received on Corporation cars and £5,390 on the Suburban Co.'s cars. Working expenses were £40,452 (increase £257), gross profit was £30,670. Interest, commissions and stamp duty required £8,574 and sinking fund £3,858. The amount provided for depreciation was £3,370, while £214 was written off property and £14,654 placed to renewal account. 17,156,050 passengers were carried and 1,585,137 car-miles run. Total income was 10·77d. per car-mile, working costs 6·13d., gross profit 4·64d., and the net balance of £14,654 (after payment of interest, sinking fund, &c.) was equal to 2·22d. Current consumed was 1·18 units per car-mile, the cost per unit was 1·08d. and the cost of current per car-mile 1·27d.

The report of the general manager, Mr. R. S. Pilcher, states that the Highland and Agricultural Show last year accounts for £500 of the difference in revenue. At the beginning of the year all the cars were equipped with meters, and £571 was saved by this means. Corrugations are beginning to appear on all the rails, and it is noticeable that where the speed of cars is increased the corrugations get gradually worse. Carborundum blocks have been fitted to a car, and it is found that corrugations are easily ground out by running this car backwards and forwards.

Bath.—The accounts of the electricity department for the year ended March last show capital expenditure £164,945 (increase £951). The total amount borrowed is £162,698 and £47,710 has been repaid or set aside for repayment.

Revenue was £19,651 and working and general expenses £10,460, leaving gross profit £9,187. After writing off £4. 13s. 7d. for bad debts, £1,661 was brought from suspense fund to meet the balance brought forward from last account, and £882 has been taken from reserve to meet interest, sinking fund contribution and £128 charged for depreciation, a debit balance of £580 being carried forward. 1,752,420 units were generated, 409,392 supplied to public lamps, 9,120 by contract and 965,177 to private consumers by meter. The total maximum demand was 1,101·6 kw. There are 187 arc and 62 incandescent lamps for public lighting.

Bradford.—The profit on the electricity undertaking during the past year was £7,399 (compared with £2,146 the previous year). Income was £3,740 more, and working and administrative expenses £1,284 less than in the previous year. Interest and sinking fund charges were £55,736 (decrease £230).

The city electrical engineer (Mr. T. Roles) states that the increase in income was almost entirely due to current supplied for power and to bulk supply consumers, and it is hoped that the further reduction in charge recently made to this class of consumers will increase the connections and thus further increase the revenue.

Epsom.—The accounts of the electricity undertaking for the year to March last show capital expenditure £39,507 (increase £2). £10,166 has been repaid out of £39,242 borrowed.

Revenue was £5,358 and expenditure £2,427, and after allowing £27 for bad debts and allowances the gross profit was £2,903 (compared with £2,064 on previous year). Loan charges were £2,718 (against £2,744) and there was a net profit of £185, compared with a deficit of £680 on previous year's working. Units generated were £299,283 (compared with 276,395), public lamps took 109,948 (106,588) and private consumers 140,932 (115,535). The total maximum demand was 198 kw. (196 kw.). The number of (equivalent) 8 c.p. lamps connected for private consumers is 18,111.

Digitized by Google

Hove.—The accounts of the Corporation's Aldrington electricity supply undertaking for the year ended March show capital expenditure £9,314 (increase £294), loan outstanding £7,905.

Revenue was £746, working and general expenses were £590, balance carried to net revenue account £156. Capital charges were £561, so that the net deficit is £404. The units purchased from Brighton Corporation were 41,407; public lamps used 7,525 and private consumers 30,914. The total maximum supply demanded was equal to 35·5 kw.

Tonbridge.—The accounts of the electricity department for the year ended March show total capital expended of £25,887, an increase of £1,007 on the year.

Income from the sale of current by meter was £2,656 and from public lighting £622, the total receipts being £3,444. Working expenses were £1,742, leaving a gross profit of £1,701 to meet interest £(789) and sinking fund instalments (£928). The net deficit was £16, against £199 243,302 units were generated; 193,493 units were sold (145,810 to private consumers and 47,683 supplied to public lamps). The total maximum supply demanded is 157 kw. (against 133 kw.).

Tunbridge Wells.—*Correction.*—In the note on page 664 of our last issue the price of current for lighting was stated to be 4¼d. This should be 4½d.

TRADE NOTES AND NOTICES.

TENDERS INVITED.

Tenders will be received by the Minister of Telegraphs, G.P.O., WELLINGTON, N.Z., up to noon Dec. 15, 1910, for supply and erection of installations of wireless telegraphy at or near Doubtless Bay, Gisborne, Cape Farewell, Sumner (near Christchurch) and Bluff. Specification, conditions, &c., at the office of the Superintendent of Electric Lines, G.P.O., Wellington, and the office of the High Commissioner, 13, Victoria-street, London, S.W., and also from Messrs. R. W. Cameron & Co., 23, South William-street, New York, and Mr. H. Stephenson Smith, 244, California-street, San Francisco, Cal. Tenders must state the name of the country in which the apparatus, &c., will be manufactured. Further particulars are given in an advertisement.

LONDON County Council invite tenders for the covering with asbestos tape of certain electric cables in manholes in the south of London. Specification, drawing, form of tender, &c., from the Clerk of the Council, Spring Gardens, S.W. Tenders must be in by 11 a.m. Aug. 30. See also an advertisement.

LONDON County Council also invite tenders for wiring and fitting for electric lighting of the second section of the central car repair depot, Woolwich-road. Specifications, &c., from the Clerk of the Council, County Hall, Spring-gardens, S.W. Tenders by 11 a.m. Tuesday, Aug. 30.

Tenders are invited for supply to the Corporation of the City of MELBOURNE of 4,840 yds. single conductor lead-covered cable, suitable for use on a circuit having a working pressure of 460 volts, and 880 yds. concentric lead-covered cable for use on a circuit having a working pressure of 2,000 volts. Specifications, forms and conditions from Messrs. Mellwraith, McEacharn & Co. Proprietary (Ltd.), Billiter Square-buildings, London, E.C., to whom tenders by noon Tuesday, Aug. 23. See also an advertisement.

Tenders are invited up to Sept. 7 for supply of battery material and glassware to the Postmaster-General's Department in QUEENSLAND. Tender forms and specifications from the Official Secretary in Great Britain of the Commonwealth of Australia, 72, Victoria-street, London, S.W. See also an advertisement.

Tenders are invited up to Sept. 20 for the supply of telegraph and telephone material to the Postmaster-General's Department in VICTORIA (Australia). Tender forms and specifications from the Commonwealth Office, 72, Victoria-street, London, S.W. See also an advertisement.

The Burgemeester en Wethouders van AMSTERDAM announce that on Aug. 22, 1910, the Corporation will receive tenders for delivery and erection of a 6,000 kw. steam turbo-generator unit for the Corporation electricity works. Specification (in German), price Fl.2.50) and further particulars from the Gemeente-Electriciteitswerken, Hoogte Kadyk 200, Amsterdam, Holland. See also an advertisement.

NEWPORT (Mon.) Electricity and Tramways committee invite tenders for supply of carbon filament electric lamps, radiator lamps (British made), flame arc lamp carbons for Excello and Oliver type lamps, and a.-c. and d.-c. two-rate and prepayment meters, during the ensuing 12 months. Specification and schedule from the borough electrical engineer and tramway manager, Mr. H. Collings Bishop, M.I.E.E. **Tenders to the Town Clerk, Town Hall, Newport, Mon., by first post Aug. 15.**

OLDHAM Surveyor's and Tramways committee require tenders by Aug. 17 for materials and labour (except electrical equipment) required in construction of a tramway. Forms, &c., from the Borough Surveyor.

CHELMSFORD Education committee want tenders by Aug. 31 for electric light wiring at Trinity-road school. Forms, &c., from Mr. W. H. Pertwee, London-road, Chelmsford.

SALFORD Tramways Committee want tenders by 10 a.m. Aug. 15 for supply of 500 tons of steel tramway rails. Specification, &c., from general manager.

DUNDEE Corporation want tenders by 10 a.m. Aug. 8 for supply of 45 tons of steel tramway rails. Specifications, &c., from City Engineer.

SOUTH SHIELDS Corporation require tenders by Aug. 8 for the supply of a travelling crane for the tramcar depot. Particulars from the Manager and Engineer.

Tenders are required by 11 a.m. Aug. 9 for erection of CHISWICK telephone exchange. Specification, &c., from Mr. J. Rutherford, H.M. Office of Works, London, S.W.

BELFAST Harbour Commissioners want tenders by Aug. 10 for the supply of 22 electric flame arc lamps. Specification, &c., from the harbour engineer, Mr. W. Redfern Kelly.

Tenders are invited for the supply of 3 tons 2 cwt. of bare h.d. copper cables to the Corporation of MELBOURNE (Australia). Specifications form of tender, &c., from the Agents of the City Council, Messrs. Mellwraith, McEacharn & Co., Proprietary (Ltd.), Billiter-square-buildings, London, E.C., to whom tenders by noon, Aug. 16.

The Deputy Postmaster-General, BRISBANE, will receive tenders until noon Sept. 7 for supply of glass cells, corks and tubes and porous cups for batteries, battery material, chemicals, &c. Specifications, &c., from the High Commissioner for the Australian Commonwealth, London. Local representation is necessary.

The Deputy Postmaster-General, MELBOURNE (Victoria), will receive tenders until 3 p.m. Aug. 30 for supply of electrical sundries, insulators, wire and sulphate of magnesia. Local representation necessary. Further particulars from 72, Victoria-street, London, S.W.

The Turkish Ministry of Commerce and Public Works want tenders by Oct. 28 (Nov. 10) for a concession for the construction and working of electric tramways in CONSTANTINOPLE and suburbs. A deposit of £13,500 (sterling) is required with each tender. Local representation is essential. Copy of specification (in French) may be seen at 73, Basinghall-street, London, E.C.

The Italian State Railways Administration, 16, Via Ludovici, ROME, want tenders by Aug. 22 for supply of 584,000 common carbons for arc lamps. Only firms on list kept by administration are generally allowed to tender. Local representation is practically necessary.

Tenders will be received at Spezia and Venice until 11 a.m. Aug. 13 for supply of electric wires and cables to the ITALIAN STATE RAILWAYS Administration. Specification (in Italian) at 73, Basinghall-street, London, E.C. Only firms on Government list are usually allowed to tender.

The Direction Générale des Ponts et Chaussées, 38, rue de Louvain, Brussels, want tenders by Sept. 11 for supply and erection of four electric travelling cranes on the tidal quay at OSTEND. The conditions are set out in "Cahier des Charges," No. 54 of 1910, which may be obtained (price 4d.) from the Bureau Central des Renseignements, 15, rue des Augustins, Brussels.

The directorate of the Austrian State Railways, Vienna, will open tenders on Aug. 7 for the erection and equipment of electricity supply works at PARDUBITZ (Austria).

LOURENÇO MARQUES Harbour & Railway Board want tenders by 2:30 p.m. Sept. 5 for supply of seven electric 5-ton quay cranes and one electric 10-ton quay crane. Conditions, specifications, &c. (on deposit of 40/6) and English translation of conditions (20/3) from the Direcção dos Caminhos de Ferro Ultramarinos, Lisbon, from the Railway & Harbour Board, Lourenço Marques, or from their agent at Johannesburg.

TENDERS RECEIVED AND ACCEPTED.

St. Pancras (London) Council received the following tenders for 21 flame arc lamps:—

Union Electric Co. (Excello), (*accepted*) **£216. 11s.**; Electrical Co. (tender incomplete, carriers not included), £86. 13s. 6d.; Foster Arc Lamp & Eng. Co. (did not supply sample lamp), £116. 7s. 6d.; Abbey Electric Co. (no carriers included, tender incomplete), £165; Arc Lamps (Ltd.) (more substantial carrier £60 extra), £183. 8s.; Gilbert Arc Lamp Co., £184; Beck Flame Lamp Co. (the tenderers suggested that present carriers will be suitable, but this was not found to be so), £189; Maxim Lamp Works, £210; Johnson & Phillips, £213; Crompton & Co. (arbitration clause and penalty objected to), £222; Oliver & Co. (includes London Electric

Digitized by Google

Firm's lowering gear; if no gear then £220), £250; General Electric Co., £300; British Westinghouse Co., £308; Jandus Arc Lamp & Electric Co., £315. 9s. 6d.

The engineer-in-chief (Mr. S. W. Baynes) reported that he had kept the lamps in the seven lowest tenders which complied with the specification under observation for some weeks—the Davy, Gilbert, Beck, Maxim, Johnson & Phillips, "Excello" and Crompton. He found the "Excello," Crompton and Johnson & Phillips lamps the most suitable for the Council's purposes, and of these three he recommended the "Excello" as the one which should be accepted, especially as this lamp had been in use outside the Council's showrooms for nearly four years with marked success.

The following tenders were received by St. Pancras (London) Council for an additional boiler at King's-road generating station :—

Edwin Danks & Co. (*accepted*), **£2,600** (cost of re-erecting if required, £200), alternative, £2,400 (£49); Hawksley, Wild & Co., £3,081 (£70); Babcock & Wilcox, £3,200 (£70); Clarke, Chapman & Co., £3,260 (£100).

Mr. Baynes' report on the tenders gave the relative grating and superheating areas of the boilers quoted for, and advised that the lowest offer be accepted. A communication had been received from Babcock & Wilcox stating that, for the efficiency guaranteed by Messrs. Danks it was essential to adopt the system of baffling, which is a subject matter of a patent of theirs for the type of boiler offered, and the firm considered it advisable to inform the Council that Messrs. Danks & Co. had recently issued a publication copying their marine type boiler and embodying a patent of theirs, and they had accordingly entered an action for infringment against E. Danks & Co., who, however, had given a satisfactory indemnity, and have agreed that 45 per cent. of the contract money should be retained by the Council until all patent rights were legally decided.

Ealing Council have received the following tenders for supply and erection of surface condensing plant.

Willans & Robinson (*accepted*)	**£2,095**
Browett, Lindley & Co.	2,700
Cole, Marchent & Morley	2,605
Davenport Engineering Co.	£2,410 and £1,984 10s.
J. P. Hall & Sons	2,385
Mirrlees-Watson Co.	3,050
L. Schwarz & Co.	£3,308 and £2,529
I. Storey & Sons	3,141
G. & J. Weir	3,670
West London Engineering Co.	1,965
Worthington Pump Co.	£2,730 and £2,160
Ledward & Beckett (evaporative condenser)	7,100

Grimsby Council have accepted the tender of Accumulator Industries (Ltd.) for supply of metallic filament lamps for street lighting, and that of E. A. Hall for fixing two 18 in. fans in the Council chamber at £20. 2s. 6d.

Leyton Council have accepted the tender of Headland & Headland (at £9. 10s.) for supplying tantalum lamps of 32 c.p., each, and an order has been placed with the Electrical Joint Box Co. for 25 additional public lighting lanterns.

Littleborough Council have accepted the tender of W. T. Henley's Telegraph Works Co. for h.t. feeder cables, l.t. distributors, road work, &c., and for transformer kiosk with transformers and equipment and switchgear in sub-station.

Stoke-on-Trent Council have accepted the tender of the Sloan Electrical Co. for 1,000 pairs of Excello flame arc lamp carbons at £20. 4s. 2d.

The North Riding of Yorks Council have accepted the tender of Cox-Walkers (Ltd.) for telephones at Northallerton County Hall and police buildings.

West Ham Council have placed an order with the British Thomson-Houston Co. for a Tirrill regulator at £83, and with the British Westinghouse Co. for switchgear at £573.

Beckenham Council have accepted the tender of O. Jones & Co., for wiring Alexandra Schools at £202.

Luton Council have accepted the tender of Clarke, Chapman & Co., for a watertube boiler and superheater, with stoker, at £1,617.

Hendon Council have accepted the tender of Waring & Gillow for wiring the Council's offices.

Rotherham Education committee have accepted the tender of Hall & Matthews for wiring the South Grove schools at £117.

Rugby Council have accepted the tender of W. T. Henley's Telegraph Works Co. for cables.

Bridlington Council have accepted the tender of the British Westinghouse Co. for 12 months' supply of metal filament lamps.

The Chloride Electrical Storage Co. are supplying a battery and Entz booster equipment for Delagoa Bay.

BUSINESS NOTICES.

Wm. J. R. Fox the younger and Arthur Brooke (trading as Fox & Co.), electrical engineers, Victoria Garage, Bradford-road, Batley, have dissolved partnership. Debts by Mr. Brooke

The telegraphic address of Mr. D. Jaroslaw, of 5, George-street, Tower-hill, London, E.C., is now "Splittings London."

The Dowson & Mason Gas Plant Co. (Ltd.) has been formed to combine the business of the Dowson Co. with that of the Mason Co., of Manchester. The Dowson gas plants will still be used for engine work, and the Mason furnaces and producers will be used for furnace work. The works of the combined company will be at Levenshulme, Manchester, and the London office will be continued at 39, Victoria-street, Westminster. Mr. Dowson will act as engineer and managing director of the combined business.

We are asked to state that Mr. E. P. Allam has disposed of his entire interests in the Premier Electric Control (Ltd.), and has now no connection with the company.

The London offices and showrooms of the British Home & Office Telephone Co. have been removed from 6, Holborn-viaduct to 15, and 17, City-road, E.C.

Plant for Sale.—Two gas driven alternator sets of 250 kw. each are advertised for sale.

Patents Development.—The proprietors of patents No. 23,878/1900 for "Improvements in process of and mechanism for separation of conductors from non-conductors," and No. 29,363/1904, for "Improvements in and relating to electrical measuring instruments," desire to enter into arrangements for exploiting same in this country. Communications to Messrs. Haseltine, Lake & Co., 7 and 8, Southampton buildings, London, W.C.

The proprietor of patent No. 21,299/1907, for a "System of directed wireless telegraphy," desires to arrange by licence or otherwise for the manufacture and commercial development of the invention in this country. Address Messrs. Herbt. Haddan & Co., 31 and 32, Bedford-street, London, W.C.

The proprietor of patent No. 18,565/1906, relating to "Electrodes for secondary batteries," desires to license British manufacturers to work the patent in Great Britain, and he is also willing to consider propositions for the sale of the patent. Address Messrs. Boult, Wade & Tennant, 111 & 112, Hatton-garden, London, E.C.

The proprietor of Patent No. 27,006/1906, relating to "Apparatus for producing oxides of nitrogen by electric process," desires to enter into arrangements for exploiting same in this country. Particulars from Messrs. Wheatley & Mackenzie, 40, Chancery-lane, London, W.C.

Science at the Japan-British Exhibition.—In connection with our note on this subject last week Messrs. H. Tinsley & Co. point out that the double wattmeter, phase shifting transformer and alternate-current potentiometer there shown were made by them and were largely designed and developed in their shops. The same firm is responsible for the manufacture of Dr. Drysdale's current potentiometer.

CATALOGUES, &c.

Siemens' Electro-medical Apparatus.—A recent catalogue of Messrs. Siemens Bros. & Co. deals with "The Skiafax." The apparatus described therein is a simple and inexpensive fixing and holding device for securing the head and all the parts of the body in any desired position during X-ray treatment. It should meet a long-felt want, in that in the majority of cases it entirely supersedes sand bags, pillows, straps and other inefficient methods of holding, involving considerable trouble and time in their preparation for use. A supplement (No. 4) deals with "X-ray Outfits with Rotating High-tension Rectifiers." This supersedes one of similar title dated April, 1909, and describes and illustrates new and improved patterns of these modern X-ray outfits, which are claimed to be superior to any other similar form of outfit now on the market. Another supplement (No. 10) is entitled "Universal Electro-medical Apparatus," and describes apparatus which has been designed as a result of long experience in connection with medical applications of electricity for cautery, faradisation, galvanisation, galvano-faradisation, light, &c. It combines all these applications in a handy and portable form, its chief qualification being that it is entirely "earth free." "Tantalum Dental Instruments" are dealt with in the last of a series of pamphlets. These instruments are made of pure tantalum metal with the usual steel handles. They are particularly suited for certain specific dental purposes on account of the fact that they are not affected by any re-agent met with in dental practice, being attacked by only one acid—hydrofluoric acid. In consequence, they may be used with all silicate cements without being affected by the cements or staining them, as is the case with steel instruments. In addition, they are very hard, and sufficiently elastic to enable them to be made fine enough to penetrate into difficult positions, which is not the case with agate and ivory, as frequently used with silicate cements.

Digitized by Google

BITUMEN CABLES AND MINING ACCESSORIES.—The British Insulated & Helsby Cables have issued a catalogue dealing with this subject, wherein is to be found just the required information on cables, both for power and telegraph and telephone work; on cable accessories, such as drum stands, shaft cleats, cable suspenders and joint boxes; and on switches, switch fuses and watertight fittings. Details are given of electric haulage locomotives, tramway fittings and accessories for overhead electric power work generally. Exploders, mining bell apparatus and telephone instruments are also dealt with. The catalogue should be in the hands of all mining engineers, representing as it does the methods by which this class of work should be carried out.

MOTOR COACHES AND LOCOMOTIVES FOR SINGLE-PHASE RAILWAYS.—An interesting brochure is to hand from the Allgemeine Elektrizitäts Gesellschaft of Berlin containing what is practically an historical account of the single-phase motor in its application to railway working. The booklet should be especially interesting when studied in connection with the Papers which have been read during the past week before the Institution of Mechanical Engineers. Excellent illustrations are given of various types of single-phase motor cars and locomotives made by the company.

BANKRUPTCIES, LIQUIDATIONS, &c.

A first and final dividend of 7s. 3d. will be payable on Aug. 11 at 10, Acresfield, Bolton, to creditors of Joseph Platt and Richd. Bleasdale, electrical engineers, Victoria-square, Bolton.

The first meeting of creditors of Harold Bristow, electrician, &c., 368, Hessle-road, Hull, will take place on Aug. 4 at York City Bank-chambers, Lowgate, and the public examination on Aug. 15 at the Town Hall, Hull.

The discharge of A. J. Hollington, electrical engineer, of 37, Walbrook, E.C., has been granted, subject to a judgment for £25 to be satisfied within a month.

The Newarc Lamp Synd. (Ltd.) is being wound up voluntarily. Mr. J. C. Young, 9, King William-street, London, E.C., is liquidator.

The Crystalate Mfg. Co. (Ltd.) is being wound up voluntarily for reconstruction. Mr. P. Warnford-Davis and Mr. J. P. Bell, both of 61½, Fore-street, London, E.C., are liquidators.

Deed of Assignment.—A dividend is to be declared under a deed of assignment executed on August 17, 1909, by Wm. G. Stillman and Hy. A. Stonham, electricians, Mount Ephraim, Tunbridge Wells. Claims to Mr. W. D. Goatly, 11, Old Jewry-chambers, London, E.C., by August 22.

COMPANIES' MEETINGS AND REPORTS.

Anglo-American Telegraph Co. (Ltd.)

The half-yearly meeting was held on Friday last, Mr. R. H. BENSON presiding.

The SECRETARY (Mr. T. H. Wells) read the notice convening the meeting and the auditors' report.

Mr. R. H. BENSON said the shareholders would be sorry to hear that the chairman of the company, Mr. Bevan, was too unwell to be present. The traffic receipts, as compared with those of last year, showed an increase of £7,000, but the amount earned by the ss. "Minia" being £10,300 less than in the corresponding period, there was, including other items, a net decrease of receipts of £2,810. The figures, after all, were for the half year only. The more important accounts were those which would be presented next January for the half-year which ended on Dec. 31. He had to touch upon a matter of general policy, and in order to make it intelligible it was necessary to shortly recapitulate the strategic position of Atlantic cables. There were to-day 16 cables laid between Europe and America controlled by four different competing parties. Seven out of 16 cables, including the four which the company owned, were in partnership for the purpose of mutual assistance and better service to the public. One of their partners was the Direct Company owning one cable; the other was the Western Union Telegraph Co., which, besides two cables, owned some 1,400,000 miles of land lines in North America. Similarly the Commercial Cable Co., with five cables, owned the Postal Telegraph Co., with 330,000 miles of land lines reaching the most important cities. In addition to the Western Union and Postal Companies, which were telegraph companies only, there had grown up a still more powerful company, the American Telephone & Telegraph Co., with over £100,000,000 sterling of capital and surplus, and which pays 8 per cent. dividend on £50,000,000 to £60,000,000 capital stock. Last winter that great company became interested financially in their partner, the Western Union Telegraph Co. There were businesses in which competition, so dear to the Anglo-Saxon heart, failed to produce the most economical results. The telephone, telegraph and cable business was an instance. It happened that the chairman of the American Telephone & Telegraph Co. was in England during the month of May on a holiday, and while he was here he gave the order to lay another cable in the Atlantic. The board viewed with great interest this order for a new Atlantic cable given by the chairman of a powerful and independent company which owned over 10,000,000 miles of land wires, of which 1,800,000 miles were trunk lines available for telegraphs as well as telephones. They were glad to find that there was no question of introducing more competition into the ocean business, and in fact the order for the new cable, although given by the chairman of the Telephone Company, was given with the intention of using it on behalf of their friends and partners the Western Union Telegraph Co., and in anticipation of their coming to terms. The prime object of this move was greater efficiency and a better service to the public to be followed by a larger business, less friction, and finally greater economy of operation. Whereas in 1896 (a year of extreme depression) the total revenue was £324,899 gross and £185,500 net, last year it was £426,753 gross and £255,644 net. Though the increase was encouraging, during those 14 years the general business of America had increased in greater ratio still, and, although our staff transmitted more than 24 per cent. more traffic than in 1908, and during the six months under review 40 per cent. more than in the corresponding period last year, they had not, nor had their partners, the Direct and the Western Union, under existing conditions and arrangements, profited as much as they were entitled to expect in the total increase of cable traffic. It was possible that if they succeeded in identifying their interest with that of the American Telephone & Telegraph Co. they might participate more largely henceforward in the growth of the business. The board were unanimous in desiring an agreement on the basis of not jeopardising present dividends and of securing besides a fair percentage of whatever increase of cable business the future might bring forth. They also wanted more unity of management, and complete harmony of the component parts in the organic whole. If this could be accomplished, and a better service offered, the board had no doubt that the public would respond by giving the company more messages. Their company, the Anglo, was agreed on principles with the American Telephone & Telegraph Co., but not yet on details. There was still much to be done. They were partners with the Direct Company and the Western Union, under an agreement which lasted for 10 more years, and no modification of it could be made without everybody's consent. If they succeeded in defining the community of interest between the four parties concerned and reached an agreement, it would be put into print and submitted to the shareholders, who would then be able to discuss it, and accept or reject it. Until then he suggested that they should refrain from putting questions which he could not answer, especially in the chairman's absence, for it was to Mr. Bevan that they owed the conduct of these negotiations. He hoped that, if they resulted in agreement, Mr. Bevan would himself be there in the best of health to submit them to the shareholders.

Mr. H. S. LEON seconded the motion for the adoption of the director's report, and

Mr. J. D. SANTILHANO having assured the chairman of the support of the Dutch shareholders in regard to the proposed agreement, a short discussion followed and the report was adopted.

London, Brighton & South Coast Railway Co.

At the shareholders' meeting on Wednesday the chairman (the Earl of Bessborough, C.V.O., C.B.) referred in terms of regret to the death of Major P. Cardew, who was a member of the board. There had been an increase of over 2,000,000 passengers and a net increase of £50,282 in gross revenue. The total increase in expenditure was £35,038, and the balance to net revenue was increased £15,244. Locomotive power expenses showed an increase of £9,092, but the item comprised both steam and electric working, and the increase might be attributed to the cost of electric current. The institution of electrical working, particularly on the system they had adopted, was admittedly a big experiment. It was not thought advisable to embark any of their own capital in erecting a generating station, and, therefore, they made arrangements with the London Electric Supply Corpn. for the supply of energy. At first only a small quantity was required, and without experience on either side it was difficult to arrange a very close contract, but now it had been decided to extend the system, and they had been able to revise the arrangement upon a very favourable basis, the working of which would produce a substantial decrease in the cost of current. The directors' report referred to the continued success of the electrical train services on the South London Railway, and the chairman said that a further portion of the suburban railways was now in course of equipment for electrical working. He told them in February of the large increase in the number of passengers which had taken place even at that early stage of the South London services, and he was glad to state that that progress had been uninterrupted, whilst there was still nothing but praise for the system from the mechanical point of view. It was too early to say much about the comparative cost of electrical and steam working, but, so far as could be foreseen, there was nothing else likely to throw any extraordinary expense upon them. In those circumstances the board felt sure the proprietors would endorse its decision to extend the system.

The present extension scheme consisted of the equipment of the railway from Peckham Rye, where a junction was made with the South London Railway, through Tulse Hill to the Crystal Palace, and from Battersea Park, where the South London Railway was joined again, through Clapham Junction, Balham and Streatham Hill to West Norwood, where the first-mentioned line was met. These lines formed a very important part of the company's suburban system, and served some of its most populous districts, most of which were intersected by the London County Council tramways. The improved services which electrification would make possible could not fail not only to bring back to the railway some of the traffic which had gone to the trams, but would also be of general benefit to the districts and in all probability produce entirely new business. Moreover,

Digitized by Google

the scheme would be of considerable advantage to the Crystal Palace, and the board had special regard to it at this moment because of urgent representations for improved services which had been made by the promotors of the Imperial Pageant, which it was proposed to produce at the Palace in the spring of next year, and the contracts for the railway works were fixed to be completed by that time. Whilst giving full credit to the elevated electric for its part in increasing the number of passengers, of which it accounted for nearly 1,750,000, he might point out that there had been a substantial gain also in the number conveyed on their main line.

Mr. DINGWALL (shareholder) congratulated the board upon the success of the electric working and upon the generally satisfactory character of the report and accounts, which were then adopted.

BAKER STREET & WATERLOO RAILWAY CO.—The gross receipts for the half-year ended June 30 amounted to £93,891. 3s. 10d., an increase of £2,380. 18s. 2d. on the receipts for the corresponding half of last year. The working expenses were £42,078. 15s. 1d., a decrease of £145. 14s. 5d. After providing for interest, rents and preference dividend, and reserving £4,000 for contingencies and renewals, £21,973. 14s. 9d. is available for dividend, and the directors have decided to pay a dividend at the rate of 3 per cent. per annum on the "A" ordinary shares and a dividend at the rate of 2 per cent. per annum on the "B" ordinary shares, leaving £2,869. 1s. 9d. to be carried forward. The number of passengers (including workmen and season ticket holders) was 14,807,736, against 14,325,065; the average receipt per passenger was 1·43d., against 1·46d.; the train mileage was 613,316, against 637,202; and the car-mileage 1,849,918, against 1,918,562.

BLACKPOOL & FLEETWOOD TRAMROAD CO.—The directors' report for the half-year ended June 30 states that the balance of profit (including sum brought forward from previous half-year and after providing for debenture interest) is £5,277. 16s. 4d. A dividend at the rate of 4 per cent. is proposed. Passengers carried were 997,574, total receipts £11,997. 0s. 1d., and car-miles run 221,356½, compared with 232,407 in the corresponding half of 1909.

CHARING CROSS, EUSTON & HAMPSTEAD RAILWAYS CO.—The directors' report states that the London Electric Railway Amalgamation Act, 1910, received the Royal Assent on July 26, and under the provisions of that act, the undertakings of this company and the Baker Street & Waterloo Railway Co. have been amalgamated with the undertaking of the Great Northern, Piccadilly & Brompton Railway Co., as on and from July 1, 1910, and that the name of the company has been changed to the London Electric Railway Co. Arrangements will be made as soon as practicable for exchanging stock and share certificates existing prior to the date of amalgamation into stock and share certificates of the new company. The gross receipts amounted to £105,626. 12s. 5d., an increase of £444. 2s. 1d. on the receipts for the corresponding half of last year. The working expenses amounted to £55,538. 19s., a decrease of £2,256. 7s. 2d. After providing for interest and rents, and reserving £3,000 for contingencies and renewals, £16,782. 19s. 7d. is available for dividend, and the directors have determined that a dividend at the rate of ¾ per cent. per annum be paid on the ordinary shares, leaving £560. 9s. 7d. to be carried forward. During the half-year 15,264,355 passengers (including workmen and season ticket holders) were carried, against 14,862,882 in the June half of 1909. The average receipt per passenger was 1·56d., against 1·63d.; the train mileage was 1,007,534, against 991,747, and the car-mileage 2,776,545, against 3,037,858.

DEUTSCH-UEBERSEEISCHE ELEKTRICITATS GESELLSCHAFT.—The report for 1909 shows gross profit M.17,631,155 (£881,558), against M.15,077,892 (£753,895) in 1908. Net profit was M.8,346,094 (£417,305), against M.7,811,581 (£390,579). A dividend of 10 per cent. is declared, against 9½ per cent. The report contains particulars of the progress made by the Buenos Ayres electricity works and the Chili hydro-electric station, the first portion of which is practically complete.

DUBLIN UNITED TRAMWAYS CO. (1896) (LTD.).—The accounts for the half-year ended June 30 show that the amount available for division is £45,191. 4s. 8d. Besides the preference dividend, it is proposed that 6 per cent. be declared on the ordinary shares, that £4,000 be reserved for renewal of cars and the balance (£7,291. 4s. 8d.) be carried forward. Passengers carried during the half-year were 26,314,318 (compared with 25,420,241 in the corresponding half of 1909) and the car-mileage was 3,811,150 (against 3,805,979). The current consumed for operating cars, lighting, &c., being 5,779,786 units (against 5,666,876).

At the meeting on Tuesday the chairman, Mr. W. M. Murphy, said a satisfactory feature of the working of the past half-year was the increase in receipts of £5,291. The gross receipts (£144,916) exceeded even the corresponding half of the exhibition year by £2,555, and the board believed the traffics would continue to grow for years to come. In addition to the ordinary expenditure they had charged against revenue the cost of lining with ferro-concrete the steel chimneys at Ringsend (£1,161. 19s.) and the cost of an underfeed automatic stoker (£309). It had been found that the underground feeder cable on a section of the Howth line where the tide flowed was subject to frequent interruptions owing to the corroding effect of the sea water on the covering of the cable, and an overhead feeder cable (costing £653) had been fixed along that section, and the cost of that had also been charged to revenue. From a promised refund of overpaid income tax, and by the aid of part of the profits of the half-year ended Dec. 31 last, £15,000 was appropriated in advance towards relaying the tram rails. The income tax authorities ultimately refunded £6,202, reducing the appropriation for relaying rails from £15,000 to £13,051. A provision of £4,000 had been made for six new double-truck top-covered cars for the Dalkey line. The board were offering to the shareholders (at £11. 10s. per share) the additional capital which they propose to raise. They had been engaged for the past three or four years in renewing the track, and they had had proof that the increasing traffic and increasing gross profits were able to meet all demands without affecting the dividends, which they had been regularly paying for the past seven years.

EDMUNDSON'S ELECTRICITY CORPN. (LTD.)—The chairman (Mr. P. Debell Tuckett) stated at the recent meeting that all-round progress had distinguished the operations last year. The expenses were reduced by over £1,000, while the loss on working the local authorities' undertakings had been reduced by £722. 13s. 10d. and the Urban Company guarantee was less by £2,505. After paying debenture interest (£10,768) and adding £14,809 brought forward, there remained £25,577, which the directors recommended should be carried forward.

GREAT CENTRAL RAILWAY CO.—The report of the directors states that good progress has been made with the electric railway between the Alexandra Dock, Grimsby and Immingham, which will shortly be ready for opening.

GREAT NORTHERN & CITY RAILWAY CO.—The report of the directors for the half-year ended June 30 states that the total revenue for the six months amounted to £39,662. 16s. 3d., and the cost of working to £19,878. 19s. 5d., equal to 50·12 per cent. of the receipts. Net revenue amounts to £19,783. 16s. 10d., which is insufficient to meet the fixed charges for the half-year, and £3,162. 16s. 8d. has been provided from outside sources. The number of passengers for the six months (including season ticket holders) was 5,966,114, against 6,041,755 for the corresponding period last year. The number of local season tickets issued during the half-year was 2,539, against 3,345. The number of three-route season ticket holders was 2,728, against 2,725.

At the general meeting on Wednesday the chairman of the company (the Earl of Lauderdale) said that the traffic showed a decrease of 75,641 passengers and of £525 in revenue, compared with the same period of last year. Of the net decrease, more than half, or £288, was attributable to local bookings, where tram competition was severely felt. Added to the deficiency in traffic revenue they had also suffered a decrease of £614 in miscellaneous receipts. On the other hand, they had reduced the working expenses by £1,161, leaving a small balance in favour of the past half year, and reducing also the percentage of working expenses from 51·56 to 50·12 per cent. As to the final result, they were short by £3,163, against £3,029 last year, and that deficiency had been balanced, as before, by a gift from those of their friends who were interested in the welfare of and had confidence in the undertaking. The bill for subway communication between their station at Moorgate, the City & South London Railway and the Metropolitan Railway had passed through Parliament, and the work would be undertaken as soon as practicable. The whole of North London had been extraordinarily affected in the last few years by the opening of the electric trams and of the Great Northern, Piccadilly & Brompton Tube. The midday traffic of ladies shopping, which used to form a regular feature of their own railway, had greatly diminished, and, for the time, at any rate, shoppers appeared to be going further afield. The convenience of the electric trams had been dearly bought at the expense of the people, but fortunately it was impossible to place any limit on the growth of London traffic, and they could only hope that their railway would ere long once more begin to attract that traffic which its convenience, speed and cheapness merited.

GREAT NORTHERN, PICCADILLY & BROMPTON RAILWAY CO.—The London Electric Railway Amalgamation Act, 1910, which has received the Royal Assent, provides for the amalgamation of the undertakings of the Baker Street & Waterloo and the Charing Cross, Euston & Hampstead Railway Cos. with the undertaking of this company from the July 1, and the name of the company has been changed to The London Electric Railway Co. Arrangements will be made as soon as practicable for exchanging stock and share certificates existing prior to the date of amalgamation into stock and share certificates of the new company. The gross receipts for the half-year ended June 30 amounted to £166,106.10s.3d, an increase of £8,113. 6s. 2d.; the working expenses were £69,602.12s.10d., a decrease of £3,802. 0s. 3d. After providing for interest, rents and guaranteed preference dividend, and reserving 6,000 for contingencies and renewals, £46,832. 0s. 3d. is available for ordinary dividend, and the directors have decided to pay a dividend at the rate of 1½ per cent. per annum on these shares, leaving £8,972. 6s. 3d. to be carried forward. The number of passengers carried, including workmen and season-ticket holders, was 19,973,049, against 19,155,883; the average receipt per passenger was 1·87d., against 1·89d.; the train mileage was 1,267,581, against 1,236,320; and the car-mileage 3,880,893, against 3,671,512. The directors express their warm appreciation of the services rendered to the company by Sir George S. Gibb, who is retiring from the board in consequence of his having accepted the chairmanship of the Road Board. Lord George Hamilton has consented to act as chairman of the company, and to fill the vacancy caused by Sir George S. Gibb's retirement, Mr. Albert H. Stanley will be appointed managing director.

HARPER ELECTRIC PIANO CO. (LTD.)—The report of the directors for the year ended June 1 last was submitted to a meeting of shareholders yesterday, and states that the business has again progressed, and that the turnover was the largest since the formation of the company. To bring about a development of the business, and to provide extra working capital, the assets were sold to the Harper Electric Piano (1910) Co. (Ltd.), the purchase taking effect from June 1 last. The directors recommended a dividend on the deferred shares at the rate of 15 per cent. (making 10 per cent. for the year) and £1,888 was carried forward.

Digitized by Google

LANCASHIRE ELECTRIC POWER CO.—At the meeting on Friday the chairman (Mr. H. F. Parshall) said the business had progressed so that it was estimated that the trading profit was now £5,000 per annum. During the past year the connected load had increased by 1,750 H.P. The average customer was about 200 H.P., and the bulk of the business was done with the cotton trade. There was something like 1,800 H.P. contracted for but not connected. The new load was largely in connection with the coal-mining industry. The price per unit had increased. £13,115 had been invested in the Power Co., and of this £9,315 had been spent on distribution, and £3,000 on the new power house. £800 had been spent on Parliamentary proceedings which prevented local authorities from operating within the company's area of supply without their sanction.

LIVERPOOL OVERHEAD RAILWAY CO.—The report of the directors for the half-year ended June 30 states that gross revenue receipts were £36,156. 16s. and working expenses £26,848. 8s. 8d. Passengers carried during the half-year were 5,090,080, compared with 4,900,216 in June half of 1909. Revenue has increased during the half-year by £824. The saving during the half-year in working charges amounts to £524, the mileage run being practically the same. After providing for working expenses and amount transferred to renewal fund (£26,848. 8s. 8d.) there was a balance of £9,308. 7s. 4d. Mortgage debentures, and calls paid in advance absorbed £4,329. 8s. 2d., leaving £4,978. 19s. 2d., and with balance forward from Dec. 31 (£4,613. 16s. 4d.) there is available for dividend £9,592. 15s. 6d. The directors recommend payment of the preference dividend, leaving £5,916. 18s. 6d. to carry forward.

METROPOLITAN DISTRICT RAILWAY CO.—For the half-year ended June 30 the capital expenditure was £51,672. The expansion of the company's traffic has been satisfactory. Gross receipts were £300,046, increase £26,727, and working expenses £143,331, decrease £4,765. On March 1 the company inaugurated a through service of trains to Uxbridge. Net revenue account shows a credit balance of £62,277, and the directors recommend dividends at the rate of 4 per cent. per annum on the 4 per cent. guaranteed stock, and at the rate of 3 per cent. per annum on the 4½ per cent. first preference stock.

SOUTH-EASTERN & CHATHAM RAILWAYS.—At the meeting on Thursday last the chairman, Mr. H. Cosmo Bonsor, said there was hardly a station on the two systems that did not show a progressive rate of business, with the exception of the lines between Victoria and Snow-hill and Nunhead. There they showed a decrease, accounted for partly by the competition of their Brighton neighbours with their electrified line. They had lost a considerable number of passengers, but not a considerable amount of money. The electrification of the Brighton line had, he was glad to say, filled that company's trains, and he could only say that the board would watch that experiment with very great interest.

At the meeting of the London, Chatham & Dover Railway Co. on the same day Mr. Robranachi said he was an advocate of the electrification by the Brighton Co. of their lines in the suburban district, and he thought the company might follow that company's example.

The chairman said they would wait to see the results on the Brighton Railway before considering anything of the kind in connection with the Chatham line.

NEW COMPANIES, MORTGAGES AND CHARGES, &c.

NEW COMPANIES.

BRACUHY FALLS AND METALLURGICAL SYND. (LTD.) (110,780)—Reg. July 14, capital £48,000 in £1 shares, to carry on the business of concessionaires, promoters, constructors and workers of tramways, railways, telegraph and telephone lines and electrical works, electricians, mechanical engineers, suppliers of electricity, &c. Private company.

CHAPMAN MOTOR STARTER SYND. (LTD.) (110,934.)—Reg. July 22, capital £5,000 in £1 shares, to adopt agreement with A. S. J. Chapman for acquisition of the invention for an improved arrangement of a combined collector ring commutator and switches for use with a small battery to start petroleum engines fitted with magnetic-igniting apparatus. First directors, T. Wilkins (manager), J. Metcalf and P. W. Chapman. Reg. office, 21, Great St. Helens, London, E.C.

GREENHILL & CRAIG (LTD.) (3,591.)—Reg. in Dublin July 25, capital £6,000 in £1 shares, to acquire the business of machinists and electrical and general engineers carried on at Belfast by E. E. Craig, as Greenhill and Craig. Private company. Reg. office, 29-37, King-street, Belfast.

HORSE POWER & SMELTING SYND. (LTD.) (111,094.)—Reg. July 29, capital £12,000 in £1 shares, to carry on the business of manufacturers of and dealers in machinery for the treatment of ores and the generation of electricity. Private company.

JOHNSON BILLINGTON ELECTRICITY METERS (LTD.) (111,063.)—Reg. July 28, capital £8,000 in £1 shares, to carry on the business of manufacturers of and contractors for the manufacture and supply of meters of all kinds, &c., and to adopt an agreement with A. M. Billington and H. S. Johnson. Private company. First directors, A. M. Billington and H. B. Spiller.

LOCH LEVEN ELECTRICITY SUPPLY CO. (LTD.) (110,980.)—Reg July 25, capital £10,000 in £10 shares, to take over so much of the undertaking of the Loch Leven Water & Electric Power Co. as relates to the supply and distribution of electrical energy (other than the supply to the factories and works of the British Aluminium Co.), to acquire supplies of electrical energy in bulk from the Loch Leven Water & Electric Power Co. or the British Aluminium Co. (Ltd.) for the purpose of distributing the same, and to carry on at Kinlochleven and elsewhere in the counties of Inverness and Argyll the business of an electric light and power company Private company.

MORTGAGES AND CHARGES.

EVERETT, EDGCUMBE & CO. (LTD.)—A memorandum of satisfaction in full of debentures dated June 9, 1905, securing £700, has been filed.

INSTITUTION OF ELECTRICAL ENGINEERS.—Mortgage and instrument of charge, both dated July 15, to secure £11,500. Property charged, 15-18, Tothill street, Westminster, and land in rear thereof. Holders, Economic Life Assurance Society.

JOHNSON-LUNDELL ELECTRIC TRACTION CO. (LTD.)—A memorandum of satisfaction in full of mortgage dated April 5, 1906, in respect of which £4,070. 14s. 6d. was outstanding on July 1, 1908, has been filed.

MUNSTER ELECTRIC LIGHTING CO. (LTD.)—Second and third debentures dated July 7, 1910, to secure £500 and £330 respectively, charged on company's undertaking and property, present and future, at Fethard, Tipperary. Holders, R. H. Bindloss and Dargue, Griffiths & Co.

NORTHAMPTON ELECTRIC LIGHT & POWER CO. (LTD.)—Particulars of £50,000 debentures, created June 23 and secured by trust deed dated July 8, 1910, have been filed. Property charged: Company's undertaking and property, present and future, including uncalled capital. Trustees, T. W. Thornton, J.P., C. A. Markham and T. E. Manning.

THOMAS BRITTAN (LTD.)—Particulars of £300 debentures, created July 5, 1910, have been filed, the whole amount being now issued. Property charged: company's property, present and future, including uncalled capital. No trustees.

RECEIVERSHIP.

MAGNETO CO. (LTD.)—Notice of the appointment of C. H. McPhers on 35, Newhall street, Birmingham, as receiver or manager, on July 18, has been filed.

CITY NOTES.

MEMORANDA (Aug. 4).—**Bank rate 3 per cent. (since June 9, 1910). Price of silver,** 24½d. per oz. Consols 81⅞—81⅞ for money; 81½—81⅝ for account. **Consols Pay Day, Sept. 1; Stock and Shares Continuation Days,** Aug. 10 and 29; **Ticket Days,** Aug. 11 and 30; **Pay Days,** Aug. 12 and 31; **Mining Shares Carry Over Day,** Aug. 9.

PRICES OF METALS (London).—*Copper*, cash, 55½; three months, 56¼. *Lead*, English, 12¾—13; foreign, 12½—12⅝. *Spelter*, 22⅝—22¾. *Tin*, English, 149—151; foreign cash, 151; three months, 151⅛. *Iron*, Cleveland, cash, 49/4, three months, 50/1.

BROMPTON & KENSINGTON ELECTRICITY SUPPLY CO. (LTD.)—The directors have declared an interim dividend at the rate of 9 per cent. per annum (4s. 6d. per share) on the ordinary shares for the half-year to June 30.

CHARING CROSS, WEST END & CITY ELECTRICITY SUPPLY CO. (LTD.)—The directors have declared an interim dividend at the rate of 5 per cent. on the ordinary shares of the West End undertaking.

CONSOLIDATED ELECTRICAL CO. (LTD.)—It is stated that the directors have declared a dividend of 3½ per cent. (less tax) on the ordinary shares for the year ended March 31.

ELMORE'S GERMAN & AUSTRO-HUNGARIAN METAL CO. (LTD.)—Shareholders have received the following notice, dated July 28:—

During the six months ending June 30 last, the sale of tubes, &c., produced at Schladern shows an increase of 5·15 per cent. in tonnage over the amount sold during the six months ending June 30, 1909. Unfortunately, the selling price has not shown the desired improvement, but in view of the increase in the demand in Germany for the class of goods produced by the Metall Co., it is reasonable to assume that the margin between the price of the raw material and the selling price of the finished article will increase rather than decrease during the latter half of the year. The weight of orders and contracts in hand amounts to 500 tons. The Metall Co. has entered into a contract for the supply of copper rollers necessary for the satisfactory and economical working of an invention which it is believed will ultimately prove of great value to the printing and allied trades. Our works manager, Mr. Ernst Preschlin, has been able to afford considerable assistance to the inventor in perfecting the process, and placing it on a commercial basis, and it is believed from the information we have at our disposal that the result will in time be satisfactory from a financial point of view.

The scheme for the re-arrangement of capital, to which the chairman referred in his speech on May 11 last, has not been proceeded with, owing to opposition by the holders of a considerable amount of debenture stock, but with an improvement in the selling price of copper tubes, coupled with a satisfactory return from the above-mentioned contract, it may not be necessary to proceed further with such scheme, and the directors have decided to allow the matter to remain in abeyance until the end of the year.

HADFIELD'S STEEL FOUNDRY CO. (LTD.)—An interim dividend of 1s per share has ben declared on the ordinary shares.

HOVE ELECTRIC LIGHTING CO. (LTD.)—For the period to June 30 the directors have declared an interim dividend on the ordinary share-at the rate of 8 per cent.

STOCK EXCHANGE NOTICES.—The Stock Exchange committee have appointed Aug. 24 a special settling day in a further issue of 100,000 £3 fully-paid 10 per cent. preference shares and £225,000 4 per cent. mortgage debenture stock of the *British Westinghouse Electric & Mfg. Co. (Ltd.)*, and have granted a quotation to £300,000 5 per cent. debentures (in lieu of scrip now quoted) of the *Amazon Telegraph Co. (Ltd.)*.

VICKERS, SONS & MAXIM (LTD.)—The directors annnouce interim dividends for the half-year ended June 30 at the rate of 2½ per cent. (less tax) on the preferred 5 per cent. stock and 5 per cent. preference shares, and 1s. per share (tax free) on the ordinary shares.

WESTMINSTER ELECTRIC SUPPLY CORPN. (LTD.)—The directors have declared an interim dividend at the rate of 10 per cent. (5s. per share), less tax, on the ordinary shares for the half-year ended June 30.

NOTES.

Railway Electrification.

WHILST many engineers consider the question of railway electrification in this country to be confined to suburban lines, others, among them Mr. J. DALZIEL, of the Midland Railway Co., believe that electric traction will be adopted for main line working in the near future. Whatever opinion is held, there can be no doubt that the recent joint discussion of this subject by American and English engineers has proved most instructive. Mr. PHILIP DAWSON, although unable to be present at the meeting, has contributed some interesting remarks to the discussion. It will be seen from his communication, which we reproduce elsewhere in this issue, that the comparisons made by Mr. H. M. HOBART in his paper are apparently based on inaccurate figures for the South London line. Thus, Mr. HOBART takes the weight of the electrical equipment as 44 tons instead of 36 tons, and calculates that the cost of electrical energy is from 10d. to 15d. per train-mile, whereas Mr. DAWSON states that the actual cost is 4·83d. per train-mile if the cost of current is taken as ½d. per unit—a figure likely to be reached at an early date. In view of the importance of reliable data, it is to be hoped that details as to the cost of operation over an extended period will soon be available for the single-phase system. At the meeting of the London, Brighton & South Coast Railway Co. last week the Chairman mentioned that it was still a little early to say much about the comparative cost of electrical and steam working, but it is interesting to notice that he had nothing but praise for the new system from the engineering point of view.

THERE is, of course, little doubt that the greatest benefits of electrification are usually experienced on suburban lines. Tramway competition in the neighbourhood of large towns has become so severe that the railway companies are faced with the loss of a considerable portion of their traffic under present conditions of working. As will be seen from a note in another column of this issue, a scheme of electrification is being considered for the Manchester district by the Great Central and London and North-Western Railway Companies. The extensive tramway system of the Manchester Corporation must have had considerable effect on the above railway companies, and if the latter electrify their lines keen competition is likely to result. In fact, it is probable that in future the tramways in many large centres of population will find the electric railway no mean competitor.

The Quadrant Electrometer.

IN his article on "The Elementary Theory of the Quadrant Electrometer," Dr. BEATTIE calls attention to certain points which are not so familiar as they might be to those persons whose duty it is to make a study, careful or otherwise, of this historic instrument. His remarks are eminently worthy of the consideration of the practical man who has to use the quadrant electrometer, and they are of no less importance to the student. Unfortunately it has become the practice among certain writers of text-books to endeavour to treat a somewhat difficult subject in an elementary and more or less popular manner; and, moreover, the practice is not confined entirely to authors, but even extends to teachers. The excuse offered is either lack of space or time; while in some cases the work is left undone out of mistaken kindness for the reader or student. Of course, what is written or said is good enough to satisfy

Digitized by Google

an examiner, and so the mischief is done. Dr. BEATTIE'S article is devoted to correcting an error which has been a feature of text-books for many years, and he does it with the greatest simplicity. He shows clearly that the controlling couple acting on an electrometer needle is not due to the suspension alone, and then proceeds to draw an interesting comparison between the electrometer and the moving-coil alternating-current galvanometer.

Central London Railway.

IT is probable that penny fares will become a permanent feature of the Central London Railway, which in its early years was almost universally known as the "Twopenny Tube." For some time the uniform fare of 2d. proved satisfactory on this railway, but diminishing traffic—due largely to the keen competition of motor omnibuses—led the directors to seek means of checking the marked decline in revenue. After due consideration, it was decided to increase the fare for long distances to 3d., while short-distance passengers were catered for by the introduction of 1d. fares. These latter naturally require to be in operation for some little time before their full effect can become apparent, but they seem already to be exceedingly popular, as may be gathered from the statement of the Chairman, Sir HENRY OAKLEY, at the meeting last week. It appears that the number of 1d. fare passengers increased in the half-year ended June 30th by 2,290,390, while the total number of passengers carried during the same period also showed an increase of 9 per cent., compared with the traffic for the corresponding six months of last year, the gain in revenue being 2 per cent. Although small, this is a move in the right direction, and it is gratifying to notice that the working expenses have not increased with the growth of traffic. One of the most interesting points to which attention was drawn last week by the Chairman was the considerable increase in "through-bookings." The co-operation between the various underground railways stands out as one of the most pleasing features of the London traffic problem, and it has certainly done much to bring the "Tubes" into public favour. Further benefit should undoubtedly result to the Central London Railway from the interchange of traffic when the extension of the railway to Liverpool-street is completed.

Electricity in Peru.—At the meeting of Ferrobamba (Ltd.) last week Mr. M. F. Kindersley said the Company had the right to utilise the water-power of the river Chalhuahuacho (Peru) and its affluents, and application had been made for similar rights on the river Apurimac. They would, therefore, have sufficient power to work the smelter, for operating a local railway system and for all other possible requirements. Electrical energy would be used for all power purposes, including the railway for joining up the Company's several properties, and perhaps a considerable mileage of the future railway system that would connect their properties with the coast would be similarly operated.

Cable Interruptions.

	Date of Interruption.
Assab—Perim	July 8, 1909
Malta—Tripoli	April 20, 1910
Reunion—Mauritius	May 20, 1910
Latakia—Palura	May 26, 1910
Obock—Djibouti	June 24, 1910
Bonny—Duala	Aug. 3, 1910

Manchester Suburban Railway Electrification.—At the recent meeting of the Great Central Railway Co., the chairman (Sir Alex. Henderson) referred to the fact that the directors of the Company, in conjunction with the L. & N.W. Rly. Co., had been considering the advisability of electrifying the South Junction and Altrincham line. It is stated that the proposal is only part of a large scheme in which the whole of the railway companies serving Manchester are concerned. The L. & N.W. Co. have already decided to give a trial to motor trains on the line between Manchester and Wilmslow, and if these are found to be a success it is anticipated that the whole of their branch lines will be electrified. The other companies are making investigations both at the local stations and at the tram termini, with a view to determining the amount of local passenger traffic at various times of the day, and the delays and inconveniences caused by the present arrangements. It is regarded as practically certain that this movement on the part of the railway companies is a general one, which will affect not only Manchester but other large centres of population.

200,000 Volt Testing Transformer. — The "Electrical World" gives an account of a 20 kw. 200,000 volt testing transformer which students in the electrical engineering school of Purdue University have recently completed, under the direction of Profs. C. F. Harding and J. W. Esterline. The material used in building this apparatus was part of that employed in the famous "million volt" transformer exhibited at the Louisiana Purchase Exposition at St. Louis in 1904, and afterwards acquired by Purdue University. The reconstructed transformer is air-insulated, and measures over-all 76 in. by 55 in. The rectangular core is 10 in. by 5¼ in. in section, and the magnetic circuit has a mean length of 222 in. The 100 volt primary winding comprises 38 turns of No. 4-0 stranded copper cable. The secondary winding is made up of 76,000 turns of No. 30 silk-covered wire, having a total resistance of 68,000 ohms. The magnetising current is 22·6 amperes, having a power component of 16·1 amperes. The transformer is to be used for research study in high-tension phenomena.

Sleeping Cars on Electric Railways.—It will be remembered that some years ago sleeping cars were introduced on the Illinois Traction System between Springfield and St. Louis, the line being electrically worked. Now, according to "The Engineer," additional cars have recently been built for a service between Peoria and St. Louis, and these embody several new features. The former cars were of the Holland type. The new cars resemble the Pullman type, but have the sections separated by permanent transverse partitions. An important feature is that the passenger, arising in the morning, can fold the berth against the side of the car, and a folding chair in the open space then facilitates his toilet. The upper berths have large windows, extending up to the eaves of the roof. Each berth has electric lights (current being supplied by storage batteries), and a small locker for watches, jewellery, &c. Permanent partitions separate the sections, and at night the sections are shut off from the centre aisle by curtains. The cars are not equipped with motors, but will be hauled as trailers, thus minimising the noise and vibration.

Terminology.—At the recent congress of the National Electric Light Association, the Committee on Terminology submitted a list of definitions for immediate publication and distribution in order to invite criticism. Among those which appear to be novel are the following: *Block rate.*—A method of charging for electric service at different successive rates per kilowatt-hour consumed, each successive rate applying only to a corresponding successive block or quantity of the total current purchased during the period covered. *Corrective motor.*—A synchronous motor running either idle or under load, whose field may be varied so as to modify the power of the circuit to which it is connected, or through such modification also influence the voltage of the circuit. *Dispersion factor.*—The factor applied to light intensity after dispersion, which gives the intensity if the dispersion agent were removed. *High frequency.*—A frequency so high that Ohm's law does not apply even approximately. *Intensified arc lamp.*—An arc lamp

Digitized by Google

with one of the carbons of small diameter to give a large current density per unit of arc, on which the arc plays thereby to intensify the light. *Operating time factor.*—The ratio of the number of hours of operation to the number of hours in the interval considered. *Operating time load factor.*—The load factor considered only during the time of operation. *Step rate.*—A method of charging for electric service at definite specified rates per kilowatt-hour consumed. A number of "factors" are also defined as follows: *Capacity factor.*—The ratio of the average station output to the maximum capacity of the station in kilowatts. *Demand factor.*—The maximum connected kilowatts of capacity divided by the actual kilowatts of demand. *Effective load factor.*—The main load of a part of the system determined by the load at the time of the system's maximum. *Load factor.*—The average load over any given period divided by the highest average load for any one minute during the same period. *Simultaneous demand factor.*—The ratio of the simultaneous demand and the connected load.

Electricity in Mines.—It is stated that the Departmental Committee of the Home Office on the use of Electricity in Mines, which has for some time past been taking evidence as to the working of the existing Home Office rules, will not take any further evidence. When the Committee resumes its sittings in the autumn, under the chairmanship of Mr. R. A. S. Redmayne, H.M. Chief Inspector of Mines, the draft report of the Chairman will at once be considered by the Committee, and it is expected that the report will be presented to the Home Secretary before the close of the present year. It will be remembered that the Committee is composed of Mr. Redmayne, Mr. Charles H. Merz and Mr. Robert Nelson, H.M. Electrical Inspector of Mines.

Obituary.—We regret to record the death on July 31st, after an operation, of Mr. W. B. Sisling, electrical engineer and one of the managing directors of Messrs. Laurence, Scott & Co., of Norwich. Mr. Sisling, who was 50 years of age, had been connected with the firm from its inception in the early eighties and was for some time the secretary of the Company, being appointed a director in 1898. He has left a large number of friends, all of whom held a high opinion not only of his business capability and integrity, but also of his technical knowledge in electrical matters.

Nickel for Resistance Thermometers.—In an article in a recent issue of the "Physical Review" Mr. C. E. Marvin remarks that whilst probably no other metal can compete with platinum for use at high temperatures, the striking advantages of nickel wire for the construction of resistance thermometers over a considerable range of moderate temperatures is not generally recognised. Nickel exhibits an inversion point between 350°C. and 400°C., and sufficient data to determine its suitability for resistance thermometers at very low temperatures are not at present available. Its greater resistance, greater change of resistance with temperature, and its small cost as compared with platinum, all render nickel better than platinum for thermometric purposes over a considerable range of temperature. While it may possibly be difficult to procure nickel wires of a uniformly high purity, yet the maximum purity seems unessential, since what passes as commercially pure nickel seems to posses the advantages required. Callendar has already shown that the temperature resistance curve of platinum is a parabola. At least three points must be located to define the parabolic curve. The nickel resistance curve seems to be very accurately represented by a logarithmic curve of the form $\log R = a + mT$, and only two points are required to locate such a curve. The coefficient m depends upon the quality, that is, the purity, and possibly some other of the physical properties and conditions of the metal. The data at present available to the author in support of the logarithmic curve are conceded to be too scanty and inadequate to demonstrate anything like a general law, but the conformity is sufficient for a great many purposes, and is shown by a table in the article. The data from the Bureau of Standards, however, are not so well fitted by a logarithmic curve. The point at 0°C., especially, is discordant; but from 100 deg. to 375 deg. the conformity is much closer. Admitting that the nickel wire temperature-resistance curve is approximately logarithmic, the author points out that resistance readings of a nickel thermometer on the usual form of slide-wire bridge, or equivalent, having a scale of equal parts, may also be made to give gas scale temperatures with very considerable accuracy.

Current Topics.

Subjects of current interest dealt with in this issue include the following:—

Mr. R. Beattie, D.Sc., contributes an article on "The Elementary Theory of the Quadrant Electrometer."

We give abstracts of the Papers read by Mr. F. W. Carter and Mr. L. R. Pomeroy at the recent joint meeting of the Institution of Mechanical Engineers and the American Society of Mechanical Engineers. Mr. Philip Dawson sent in a written communication in connection with the discussion on railway electrification at the same meeting.

We continue our account of the work carried out at the Reichsanstalt during the past year.

A memorandum has been prepared setting forth the objects of the Association of Consulting Engineers.

We analyse the accounts of the Manchester Corporation Tramways Department for the year ended March 31st last.

Wimbledon Corporation have received sanction for borrowing £6,600 for mains, house services and meters.

"Telephonist" contributes a communication on the subject of the National Telephone Co.'s position. His communication is open to much destructive criticism, and the writer is wise to prefer anonymity.

Hereford Corporation have received sanction to a loan of £3,500 for mains and services.

Companies' Meetings and Reports.—At the Central London Railway Co.'s meeting last week resolutions authorising the raising of £480,000 share capital for constructing the Bank-Liverpool Street extension line were approved.

At the meeting of the Great Central Railway Co. last Friday Sir Alex. Henderson said he had reason to believe that the improved telephone service which was now available all over the country had affected railways by enabling business to be carried on with a fewer number of journeys between place and place. Sir Alex. Henderson also referred to the probability of electrifying the Altrincham line, which was jointly owned by the L. & N.W. and G.C. companies. A final decision has not yet been arrived at. (It is stated that the railway companies serving Manchester are considering a scheme for the electrification of all the Manchester suburban lines.)

The Liverpool Overhead Railway Co. are able to pay the 5 per cent. dividends on both classes of preference shares for the first time since 1907.

The directors of Brown, Boveri & Co. report a somewhat unsatisfactory year's work owing to the steady fall in prices, and they deplore the continued difficulty of obtaining contracts which leave a margin of profit to the manufacturers.

At the meeting of the Metropolitan District Railway Co. on Wednesday the chairman (Sir Geo. S. Gibb) was able to present a very satisfactory report of the progress of the Company. There was a large increase in the number of passengers, and expenses had decreased. He stated that the financial position had been improved and that the outlook was very encouraging.

INSTITUTIONS AND SOCIETIES.

THE TRAMWAYS AND LIGHT RAILWAYS ASSOCIATION.—The Official Circular of this Association for July contains Mr. J. A. Panton's reply to the discussion on his Paper, "Brake Shoe Standardisation," read at the Dublin Congress; a report of the valuation appeal by the Glasgow Corporation, with opinions of Lord Dundas (April, 1910) and Lord Shand (March, 1873); a full report of a case in regard to Parliamentary deposits, which was recently decided, with judgment by the Master of the Rolls in Court of Appeal, April, 1910.

Digitized by Google

MANCHESTER CORPORATION TRAMWAYS.

The tramways undertaking of the Manchester Corporation has certainly proved a very profitable investment for the ratepayers, as may be gathered from the fact that during the last nine years a total sum of £452,000 has been handed over by the Tramways Committee in relief of the rates. The contribution for the year ended March 31, 1910, is the largest so far recorded, namely £75,000, compared with £70,000 in 1908-9. As the renewals and depreciation fund stands at £422,210, with a total capital expenditure of under £2,000,000, and £284,812 has been applied in the reduction of debt, the City Council may well regard the future of the undertaking with equanimity.

In their report for the past year the Tramways Committee state that the aggregate length of single track open for traffic is now 181 miles 1,351 yds., including the lines over which the Corporation are exercising running powers.

The total number of passengers carried during the 12 months was 159,049,096, an increase of 4,037,212 compared with the previous year's figure, and the largest number of passengers recorded. As the number of car-miles run decreased from 17,316,753 to 17,161,774, it is not surprising that the average traffic revenue has grown from 10·728d. to 10·869d. per car-mile during the year, and the average number of passengers from 8·95 to 9·26. The population served by the tramways is estimated at 850,000, so that the average number of journeys per head of population per annum is now no less than 187, as against 182 a year ago. This steady increase in the habit of "tramming" must be regarded by the Committee with favour.

It is interesting to notice the proportion of passengers carried at the various fares. This is given below, and seems to show that the increase in traffic is mainly at the lower fares.

	1909-10. Per cent.	1908-9. Per cent.	1907-8. Per cent.
½d.*	8·40	7·35	6·92
1d.	67·10	67·04	67·82
1½d.	13·36	13·14	12·80
2d.	6·65	7·28	7·24
2½d.	2·09	2·05	2·10
3d.	1·62	2·05	1·80
Fares above 3d.	0·78	1·09	1·32

The total number of units used by the cars was 29,335,144, or 1·709 units per car-mile, compared with 1·748 units in the previous year and 1·76 units in 1907-8. This steady decrease in the consumption of energy, in spite of an increase in the number of passengers per car-mile, is worthy of note. The current, as will be seen from our analysis of the accounts, is purchased from the Electricity Committee at the average price of 1·01d. per unit.

The total number of cars in stock at March 31, 1910, was 582. Of these cars 321 were of the single-truck type, 216 had double trucks and 45 were combination cars. It may also be mentioned that 310 cars have covered tops. During the year 15 new cars (the bodies for which were manufactured in the tramway department's workshops) were put in service, whilst a further 35 cars were nearing completion.

The system of parcel carrying commenced in October, 1906, on these tramways, and has developed considerably since its inauguration. This is indicated by the fact that, on an average, 16,072 parcels are now dealt with every week, compared with 12,942 last year and 9,101 in 1908. The total receipts for the year under this heading are £8,678 and the total profit £2,264.

From the analysis which we give below of the tramway accounts it will be noticed that the working expenses have increased by 0·10d. per car-mile, and are now 7·15d. per car-mile. This result is mainly due to the increased payment for local rates, no less than £38,498 being paid under this head, an increase of £6,148 or 0·09d. per car-mile, compared with last year's figure. In the analysis of the accounts below, the cost per car-mile for the previous year is also given to facilitate comparison.

* ½d. fares are adopted on the circular and cross routes only, not on the main routes.

		Cost per car-mile. 1909-10.	1908-9.
Traffic Expenses.			
Superintendence	£2,154	0·03d.	0·03d.

Miscellaneous	1,192	0·02d.	0·02d.
Total Capital Charges, &c	£133,321	1·87d.	1·78d.
TOTAL EXPENSES (*inc.* capital charges)	£644,391	9·02d.	8·83d.
Revenue.			
Traffic revenue	£777,219	10·87d.	10·73d.
Rents, sundries, &c.	8,546	0·12d.	0·12d.
Parcels department	2,264	0·03d.	0·02d.
Bank and other interest	5,431	0·08d.	0·04d.
TOTAL REVENUE	£793,460	11·10d.	10·91d.
Balance	£149,069	2·08d.	2·08d.

This balance is allocated as follows :—

Reserve, renewals and depreciation fund	£70,021	0·98d.	1·06d.
Street improvements, &c.	4,048	0·05d.	0·05d.
Contribution in aid of rates	75,000	1·05d.	0·97d.

As mentioned above, the reserve, renewals and depreciation fund now stands at £422,210. During the past year sums of £41,547 for renewal of permanent way and overhead equipment, and of £7,088 for renewal of cars and car equipments, were taken from the fund.

The capital expenditure during the past year amounted to £120,504, £43,036 of this being on account of the Princess-road car-shed buildings, £22,621 for new cars and £33,779 for permanent way. The total expenditure on the electric tramways to March 31, 1910, was £1,957,594. The various items comprised in this total are as follows, the percentage each bears to the total outlay being also given :—

		Per cent.
Permanent way	£645,495	33·0
Overhead equipment	181,306	9·3
Depots and car sheds	381,869	19·5
Cash offices	3,940	0·2
Rolling stock	388,414	19·8
Machinery and plant	13,039	0·7
Office furniture	6,472	0·3
Cost of Carriage Co.'s undertaking	291,553	14·9
Preliminary expenses	25,751	1·3
Promotion expenses	19,755	1·0
	£1,957,594	100·0

ELECTRIFICATION OF SUBURBAN RAILWAYS.*

BY F. W. CARTER.

Summary.—The author considers there is little prospect of the general electrification of the railways of this country, but believes that an investigation of the cost of electrification and the economic results of providing improved facilities would in many cases justify the conversion of suburban railways to electrical working. Interesting particulars are given of the cost of conversion, the maintenance of electrical trains and of train delays, together with brief descriptions of the electric lines in this country.

Many of the railways of this country have, so far as their suburban passenger traffic is concerned, been affected very adversely in recent years by the great and increasing competition of tramcars and motor omnibuses. The companies concerned appear undecided at the present between giving up a great portion of this class of traffic permanently and endeavouring to regain it by electrification of their suburban lines. The latter expedient, although an expensive one, has hitherto invariably been found successful in regaining much of the lost traffic, and the problem confronting a company in regard to any section of its suburban lines is that of determining whether the expected gain from electrification will justify the expense to be incurred.

Modern electric railway apparatus leaves little to be desired in the matter of freedom from breakdown, the delays from all causes, electrical and mechanical, for the month of December, 1909, averaging about 33 seconds per day per train on the District Railway and only 2½ seconds per day on the Underground Electric Railways' tubes. The total cost for maintenance and repairs of rolling stock on these lines does not exceed 0·6d. per car-mile.

In typical suburban service the greater part of the energy input is used in accelerating the train, and the energy consumption per ton-mile depends principally on the nature of the schedule. A high initial rate of acceleration involves great mechanical strains on the bogies, and should not be employed unless the difficulty of the schedule renders it necessary. The equipment losses during acceleration are of the same order of magnitude in the continuous current and the single-phase systems, in spite of the rheostat losses in the former system. The performance of a given electric train under given conditions of suburban service can be very closely predetermined, for the factors liable to uncertainty have but small effect on the result. Schedule calculations, however, are inadequate by themselves to determine the question of the suitability of an equipment, as the limiting features are usually connected with the heating of the motors, which again depends on the energy loss in the motors. This loss is much greater in the single-phase system than in the continuous-current system.

There appears little prospect of general electrification of the railways of this country, as no advantage is apparent which would in any way justify the expense. It is only in the case of heavy suburban service that there is prospect of commercial advantage accruing from electrification, and whilst there may be other local opportunities for electrical working, there is at present no indication that the steam locomotive can be superseded with advantage for ordinary main line work.

The extensive tramway systems that radiate from most of our large cities and motor-omnibuses have resulted in a great shrinkage of suburban railway traffic. The railway companies affected appear for the most part undecided between allowing their short-distance traffic to go, employing their energies in fostering the longer-distance traffic, and endeavouring to reduce the effective range of tramway competition by electrification of their suburban lines. The latter alternative, wherever it has been tried, has invariably succeeded in recovering a portion of the lost traffic, besides creating a more desirable traffic for longer distances by the improvement of facilities. Whilst it is by no means certain that local electrification would prove the best commercial policy in the case of all railways handling suburban traffic, it is the author's opinion that there is considerable scope for well-considered electrification schemes in this country. Where a suburban railway is regularly used to near the limit of its capacity and there is still possibility of increased traffic, there is every reason to expect a commercial advantage from electrification. The capital cost is further justified by the greater use that can be made of existing lines and terminals under electrical operation. The cost of electrification should in fact be set against the cost of widening and improving the railway to accommodate the traffic in view.

In the more usual case, however, the management of a railway are compelled to estimate the chances of success from far less certain data, the difficulty confronting the management being to estimate the increase in receipts which would accrue from the improved facilities. The capital outlay and operating expenses can be closely approximated in any particular case, and the amount will depend largely on the difficulty of the proposed schedule. It is in the power of electricity to improve very greatly on the performance of steam trains; but the greater the improvement the higher the capital and operating costs and the greater the attractiveness of the line. It is a matter of nice estimation and computation to determine what improvement of service will result in the greatest commercial advantage to the railway. The Tynemouth lines and the Liverpool–Southport line do not differ greatly in the distance between stops. The schedule speed, however, is considerably higher on the Liverpool–Southport line, and the effect of this on operating expenses partly accounts for the experience of the Lancashire & Yorkshire Railway that the cost of electric working, as they had expected, was, when proper allowances were made for the depreciation of the more costly plant, slightly higher per train-mile run than that of steam working.

The electrification of a steam railway can of course be considered commercially expedient only when the estimated net profit under electrical operation exceeds that under steam operation by more than the interest on the extra capital involved. It is chiefly the burden of capitalisation which limits electrification to lines of heavy traffic. The extent of the burden is in practice very variable. The total capital involved in the Tynemouth electrification to date is approximately £244,000, and the annual electrical train-mileage, 1,215,000; taking the interest at 4 per cent. the capital burden is seen to be about 1·93d. per train-mile. Again, the capital involved in the electrification of the South London elevated line has been given as approximately a quarter of a million sterling, and the yearly train-mileage is at the present time some 375,000, to be eventually increased to approximately 585,000 miles. The burden of the capital is therefore about 6·4d. per train-mile at present, decreasing to 4·1d. if the improved service can be realised without adding to the capital expense. The capital burden in the case of the Mersey Railway has been given as 4·3d. per train-mile, and in the case of the Lancashire & Yorkshire electrified lines as about 2d. per train-mile. These two cases of course include generating station, which is absent in the first two.

An indispensable requirement to the success of any system for working suburban traffic is immunity from all forms of breakdown competent to delay the service. In this respect modern electric railway apparatus, if chosen with reference to the nature of the service and maintained with care, leaves little to be desired. Even when first installed the troubles are usually of a minor character, and the consequent delays unimportant, whilst ordinary operation is exceedingly reliable so far as the electrical plant is concerned. Table I. gives particulars of all delays on all lines of the Underground Electric Railways Co. of London for the month of December, 1909. The much greater loss of time on the Metropolitan District Railway, as compared with the tube lines, is almost entirely due to the fact that District trains operate to a considerable extent over foreign lines, worked for the most part in the interests of steam trains. The comparative immunity from breakdown is duly reflected in the low maintenance cost of the train equipments. Mr. Chapman dealt with this subject at a valedictory dinner given in his honour on February 7, 1910, on the occasion of his retirement from the position of chief engineer to the Underground Company. He said that they (the Underground Railways Company) "owned over 800 motors, and that every one was the same throughout, no matter whether it was working on the District or a Tube, under a car or on a locomotive, all were interchangeable; and to-day, several years after the original purchase, they were negotiating for some more of the same motors to meet the increased traffic requirements of the District Railway. On no one of their properties did the cost of rolling-stock maintenance and repairs exceed 0·6d. per car-mile. The 10 District Railway electric locomotives, now five years old, made 1,300 miles per day at a cost of ½d. per mile for all maintaence and repairs. Two of them coupled handled a London & North Western Railway nine-coach train to Mansion House far better than a steam locomotive had ever done. The maintenance cost was 1d. per train-mile. The North Western costs for maintaining a steam locomotive were 4d. per mile; the average cost for all English railways was 3½d. per mile."

The railways in this country operated wholly or in part electrically are 18 in number, working over a total of approximately 200 miles of route and 410 miles of track. The trains are worked by 87 locomotives and 821 motor-coaches. The aggregate nominal power of the driving motors is approximately 360,000 H.P., of which 184,000 H.P. is provided by one type of motor alone, namely, that used exclusively by the railways operated by or in conjunction with the Underground Electric Railways Co., London, and partly by the Metropolitan Railway.

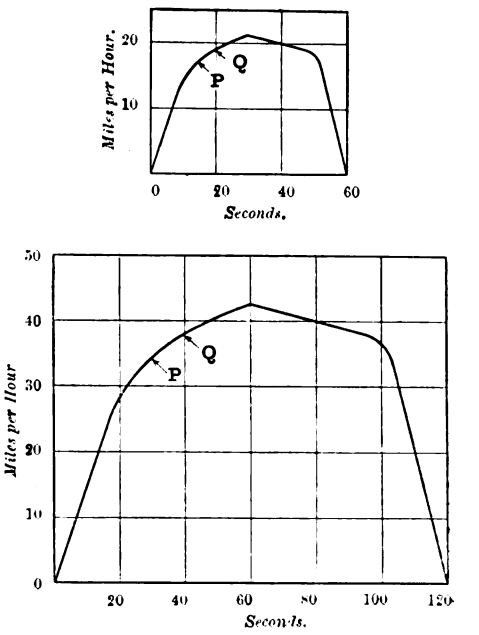
Average delay per train per day due to electrical troubles on the trains....mins.	0·062	0·029
Average delay per train per day due to all causes mins.	0·548	0·042

The author proceeds to give a brief comparative summary of the electric lines in this country. By far the greater portion of the electrically operated traffic is worked by motor-coaches rather than separate locomotives. This method of operation is peculiarly adapted for working suburban railways and will no doubt remain the standard. The chief advantage of locomotive operation is that the greater portion of the electrical apparatus is immediately under the eye of the driver. If the apparatus was less immune from breakdown this would be worth making considerable sacrifice to attain, but practically the advantage is small, as balanced against the advantages of motor-coach operation. The multiple-unit system of control in which the motors on any bogie and the corresponding motor controllers form a unit—all such units on a train being operated from the driver's cab—is practically universal in the latest equipments, as well for locomotives as for motor-coaches. Most of the multiple-unit trains used on surface lines carry the motor-controlling apparatus suspended on the underframe of the motor-coach. In the case of the tube lines, however, it is invariably located inside the motor-coach, in order to be accessible in case of emergency. In the smaller tubes the control compartment is placed over the motor-bogie on a raised platform.

Most of the passenger coaches are of the saloon type; there is, of course, nothing in the nature of electrical working to render this type of coach indispensable, although the shortness of the station stops and the high rate of acceleration usual in electrical service render it preferable from the operating point of view. Some of the most popular of the Metropolitan Railway trains, however, are of the compartment type, being bogie trains, dating from the time of steam operation, converted for electrical working. The London, Brighton & South Coast Railway have sought to combine some of the advantages of both types of coach in the new rolling-stock for their South London Elevated Electric line. The coaches are of the corridor type, being divided into compartments, and having side doors, but having a corridor running the length of the coach for distributing the passengers. Although most of the railways in this country employ the vacuum brake, the electric railways, with the exception of the Lancashire & Yorkshire and the Midland, have adopted the Westinghouse type of brake. The chief reason for this is that compressed air can be stored to take off the brakes at a moment's notice.

In suburban service the greater part of the energy expended is used in giving speed to the train and is ultimately dissipated in the brakes. Other things being equal, therefore, the more frequent the stops the greater is the energy required per mile, and the more difficult the service. The energy-consumption per ton-mile, unless abnormal, is, in fact, a very good measure of the difficulty of a service. If this were more generally realised the world might be spared some of the absurd comparisons of energy-consumption between different systems, in which credit is claimed for obtaining a low energy-consumption, which is really due to comparatively easy service. If it be granted that the natural and normal energy-consumption per ton-mile is a reasonable measure of the difficulty of a schedule, an even more reasonable measure is to be found in a certain acceleration immediately expressible in terms of the particulars of the service, namely, the acceleration that would cause the train to reach a speed equal to the mean running speed in a distance equal to that between stops. This is merely a dynamical result, and in order to show it let Figs. 1 and 2 represent speed-time curves corresponding to two schedules, the curves being such that that of Fig. 2 is simply that of Fig. 1 magnified twice in every direction. The distance represented in Fig. 2 is then four times that in Fig. 1. At corresponding points P on the two curves, the acceleration, and therefore the tractive effort per ton necessary to produce it, will be the same. The power per ton required at P to produce the acceleration, being proportional to the tractive effort and speed, is twice as great in Fig. 2 as in Fig. 1. The energy per ton required to accelerate between corresponding points P and Q, being proportional to the power and to the interval of time will be four times as great in Fig. 2 as in Fig. 1. But the distance is also four times as great, and thus the energy per ton-mile used in accelerating—probably some two-thirds of the whole—is the same for the two services. If the mean train-resistance per ton were the same for the two curves, the energy per ton-mile required to overcome the resistance would also be the same, and we might then assert that the total energy-output per ton-mile would be the same in the two cases. As it is, there is a small error affecting a comparatively small portion of the energy, which will have to be neglected. This is in general of little consequence in cases in which it would be expedient to employ the result, that is, in suburban service, where a ratio of four to one in distance with simliar speed curves, is, of course, a very exaggerated case. It will be seen that the acceleration referred to above, which will be called the specific acceleration of the schedule, is the same for the two curves, being the square of the mean running speed divided by twice the distance. It will also be seen that the method is perfectly general; so long as the speed-time curves for two services are similar the specific acceleration will be the same, and the energy output of the equipments practically the same. It follows that of two services, that having the higher specific acceleration may be expected to show the higher energy consumption per ton-mile. Also that if two services have the same specific acceleration but differ in energy consumption the higher can be reduced, in so far as it is not due to lower equipment efficiency, by running so as to assimilate its speed-time curve to that of the lower. The specific acceleration of a schedule is a better index of the difficulty of the schedule than the energy-consumption, inasmuch as it is independent of the equipment efficiency and of the particular manner of running the schedule, in effect reducing equivalent services to the same mode of operation. This, of course, presupposes that the line is not specially graded to reduce the difficulty of operation.



FIGS. 1 and 2.—SPEED-TIME CURVES CORRESPONDING TO TWO SCHEDULES.

The above is an application of a method which the author has more fully elaborated elsewhere.* Table II. gives some characteristic schedules arranged in order of difficulty as indicated by the specific acceleration.

A difficult service—in the sense of a service in which the specific acceleration is high—is one in which it is advisable, in the interests of low energy-consumption, to employ high rates of acceleration and retardation; in an easy service this is of smaller consequence and hardly worth securing at the cost of heavy mechanical strains on the bogies, &c., with the great draught of power incident to the use of a high rate of acceleration. The account of the tests on the Liverpool overhead trains indicated a maximum rate of acceleration of 4·2 ft.

per second per second (2·9 miles per hour per second), and this is perhaps as high as it is advisable to employ in service.

During the period of acceleration by controller notching, considerable energy loss is inevitable in the equipment. In the continuous-current system the average equipment efficiency during notching is usually only about 57 per cent., the remaining 43 per cent. being lost in the motors, rheostats, &c. It has been hastily assumed by some that the avoidance of rheostat losses in the single-phase system would result in much lower losses and higher mean efficiency during notching. That this is an unwarranted conclusion is shown by the authors of a recent Paper on the Heysham electrification,† who, although by no means blind to the merits of the single-phase system, found as the result both of test and calculation, that the mean efficiency of the equipment during notching was only 56 per cent. in the cases considered. The efficiency after notching is, of course, considerably higher for continuous current than for single-phase equipments.

The claim that the performance of a suburban electric train can be very closely predetermined may seem an extravagant one, until it is considered how very few are the conditions on which it depends. The quantities most likely to be subject to some uncertainty beforehand are the voltage at the train and the train-resistance. In suburban work, however, a small error in these has but little effect either on the schedule speed or energy-consumption. Perhaps an idea of the accuracy with which the running can be predetermined will be best conveyed by disclosing that the author's practice, in making a guarantee of energy-consumption, is to compute it as closely as possible under the expected conditions of test and add 5 per cent. to cover bad driving and other unforeseen contingencies. Such a guarantee would, of course, be of little use unless accurate instruments were available for making tests. Train-testing instruments should be specially designed for the work, so as to secure exceptionally large torque and heavy damping. The delicacy of ordinary stationary instruments renders them useless for train-testing where they are subject to great vibration in all directions.

These schedule calculations are easy and commonplace but quite inadequate by themselves to determine whether an equipment is suitable for a given service. More important in this connection are the calculations involving the magnitude and distribution of the losses in the motors, with the facilities for transferring and dissipating the heat generated. Such calculations, however, are almost necessarily confined to the designers of equipments, as the data on which they are based are not generally available. In order to give a rough idea of the quantities involved, it may be stated that the ultimate temperature rise of the hottest accessible part of an ordinary railway motor, totally enclosed and without forced ventilation, as measured by Centigrade thermometer after continuous service, is given approximately by $T=7Ww^{-\frac{1}{3}}$, where W is the mean motor loss in service (not including gear loss) in watts, and w is the weight of the motor in pounds, excluding gear and gear case. The motor losses in suburban service usually take from 6¾ per cent. to 7 per cent. of the input to the driving equipment‡ in the continuous-current system, and from 15 per cent. to 18 per cent. of this input in the single-phase system. The great motor losses incident to the single-phase system form the foundation of all the objections raised to the use of this system for suburban service.

The heating of the motors has always been a limiting feature in the design of equipments for this class of service, and the practicable and desirable means of dealing with it are well understood. The use of forced draught for cooling the motors, whilst practicable for locomotives and single cars, is quite out of place on multiple-unit trains intended for suburban service, where, since the equipment may not be inspected for hours together, it cannot fail to lead to breakdown, increasing maintenance charges and causing delays to traffic.*

Fig. 3 gives speed, power and motor-loss curves corresponding to typical suburban schedule runs with continuous current and with single-phase equipments, the former of which carries 20 tons per motor and the latter 23 tons. It will be seen that the great difference between the systems is in the motor loss, which amounts to 6·75 per cent. of the input in the continuous-current case and to 17·8 per cent. in the single-phase case. Although both motors are dynamically capable of working the service, the former alone has sufficient thermal capacity for the purpose, the other having to dissipate three times as much energy as it can get rid of by natural cooling.

The author has confined his remarks to the subject of "Suburban Electrification," inasmuch as there appears little prospect at present of general electrification of railways in this country. The properties which give to electrical working its predominant advantages in the case of heavy suburban service become of minor importance when the distance between stops is considerable and the service infrequent. Even in the case of heavy suburban service, moreover, the margin in favour of electrification is by no means overwhelming. This much can be affirmed, however, that where there is any considerable suburban traffic, an investigation of the cost of electrification and the economic results of providing improved facilities will repay the trouble and expense, and in many cases justify proceeding with the conversion.

The above remarks are intended to apply to the electrification of existing steam-operated lines. The case of entirely new railways is different and much more favourable to electrical operation. In laying out a new branch to an existing railway, again, it may be well

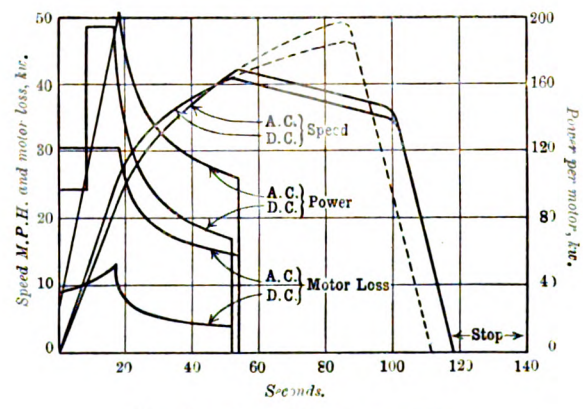

Fig. 3.—Train Characteristics.

worth while to consider electrical operation, the capital cost of which might be more than saved in the cheaper roadbed, since steep grades are much less objectionable on an electrical than on a steam road. There are also likely openings for local electrification on existing railways even apart from suburban systems; and again, where electric power is already available at goods yards and docks, the shunting might be more efficiently carried out by specially designed electric locomotives, fed perhaps by a suitable surface-contact system, than be steam locomotives. For ordinary main-line work, however, there is at present no indication that the steam locomotive can be superseded with advantage in this country.

The Braking of Alternating-Current Motors.—In a recent number of "L'Industrie Electrique," Mr. A. Héreny suggests a method for quickly braking induction motors by providing a suitable excitation for the stator during the act of stopping, thus enabling the rotor to generate alternating currents and to absorb energy. This may be attained by coupling a small series direct-current machine to the motor, connected so that when the main circuit is opened, the direct-current machine is coupled to one of the stator phases and excites the field, while the rotor is either short-circuited or connected to a resistance. Alternatively a rectified current derived from one of the rotor phases—in the case of a wound rotor with slip rings—may be used to excite the stator field, the current being rectified either by an electrolytic valve, a commutator, or other means.

COHERERS.*

BY W. H. ECCLES, D.SC., A.R.C.S.

Summary.—A method of investigating detectors is developed with special reference to the relations between the energy given to the detector in the form of electrical vibrations and the energy delivered by the detector, as direct current, to the circuit of the indicating instrument. The response of the detector was measured by comparing the sound in its telephone with the sound produced in the same telephone by interrupting a measurable direct current. The results of experiments on coherers made of oxidised iron wire dipping into mercury, and on coherers made of a clean iron point touching an oxidised iron plate, are recorded. The author puts forward the hypothesis that the properties of an oxide coherer may arise solely from the temperature variations caused in the minute mass of oxide at the contact by the electrical oscillations and by the applied E.M.F. He examines the hypothesis mathematically and shows that most of the phenomena recorded can in this way be accounted for as perfectly as the present state of the measurements permits.

It is well known that an imperfect contact between almost any pair of good electrical conductors suffers a change of resistance when electrical oscillations of sufficient intensity occur in the circuit containing the contact. Prof. Branly, in 1896, concluded after much investigation that the effects observed were due to a modification of the electrical conductivity of the film of dielectric that happened to separate the conductors. For example, a mass of metal filings melted down in resin showed appreciable alteration of resistance when a spark or discharge occurred near it; and a pair of pieces of metal in very light contact, yet separated by their surface films of condensed gas, showed the phenomenon excellently. Sir Oliver Lodge at that date held the view that the alteration of resistance, usually a diminution, was due to the piercing of the dielectric and a consequent cohesion of the metals. He gave the name "coherer" to instruments exhibiting or utilising the phenomenon, and this name has been universally adopted and the suggested explanation widely accepted. It has often been pointed out that Lodge's explanation is inapplicable to known cases where the resistance of the coherer is increased by the passage of electrical oscillations. In the present Paper it will be shown that there is no need to adopt the "cohesion" hypothesis, even in the case of typical coherers where the resistance is lowered by the action of electrical oscillations.

Ten years ago the known ways of investigating a coherer required the device to submit itself to powerful electric discharges. We find investigators of filings coherers watching the sparks between the filings and boasting of fusing the filings into chains of quite considerable tenacity. But the engineers who were at that date nursing the infant wireless telegraphy were, on the whole, more gentle with the coherer than were the men of science. At most, the engineers required that the current through the coherer when it "cohered" should work a delicate relay. A few years later they merely asked that the coherence current should move the diaphragm of a telephone receiver. The oscillatory voltages that need be applied to a coherer in order to produce a resistance change perceptible by an ear at the telephone are very small indeed; and in these cases a good coherer spontaneously and very perfectly recovers its original resistance when the oscillations cease. The "cohesion" explanation appears improbable here, though in the cases familiar 10 years ago, where the alteration of resistance is permanent, that explanation seemed plausible.

Within the past six years the problem of the coherer has often been attacked, and each observer has in turn found all the theories of the action of coherers insufficient to explain his experiments, and has added some suggestion of his own. For example, A. Blanc,† in 1904, concluded that neither oxide nor condensed gases played a part in certain coherers, and believed that particles of the two surfaces diffuse at a rate depending on the current, temperature and pressure. On the other hand, Robinson‡ decided that in single point coherers the resistance is that of an elastic film of oxide, and that permanent coherence implied injury or thickening of the oxide: while Huth§ attributes coherence to the ionisation of the film rather than to the thickening of the oxide. From the point of view of the results of some of the experiments to be described in this Paper, the observations of A. H. Taylor are of special interest. He found that the current through a single point steel coherer shows three stages as the gap is diminished. In the first stage there is a feeble leakage current due, he thinks, to vapour conductivity; in the second, conduction due to metallic ions (in this stage a small rise of E.M.F. produces a great increase of current); in the third stage ordinary conduction occurs. In a Paper entitled "Recherces sur les Contacts Imparfaits" ("Journ. de Physique," ser. 4, III., 1904, p. 350), A. Fisch describes his experiments on the voltage-current curves for a coherer consisting of two spherical surfaces of steel whose separation was capable of fine adjustment. He found, from a study of numerous curves, that the average curve exhibits three stages: (1) As the current is raised the P.D. across the contact increases more and more slowly to a critical value constituting stage (2), where, though the current increases, the P.D. remains constant. Then (3) increasing current is accompanied by continually rising P.D. This curve of Fisch's is precisely the curve II. of Fig. 8 below. Besides these investigators there are others who have advocated that the electrostatic attraction between the conducting surfaces may account for the phenomena.

Very few, if any, experiments with electrical oscillations of very minute measured voltages have so far been published, yet only minute voltages nowadays arise in practice. The purpose of the present investigation is to examine the action of a certain kind of coherer under "weak signals," especially in respect of their energy relations.

Method of Experiment.—The self-restoring coherer to be examined was placed in a circuit comprising the necessary source of steady E.M.F. and a telephone receiver. At the same time it was also connected in series with a condenser, to form, as in practical wireless telegraphy, a shunt across the condenser of an oscillatory circuit (Fig. 1). This oscillatory circuit was made a secondary circuit in relation to a tuned primary oscillatory circuit. The coupling was always extremely loose. Trains of damped oscillations, of maximum

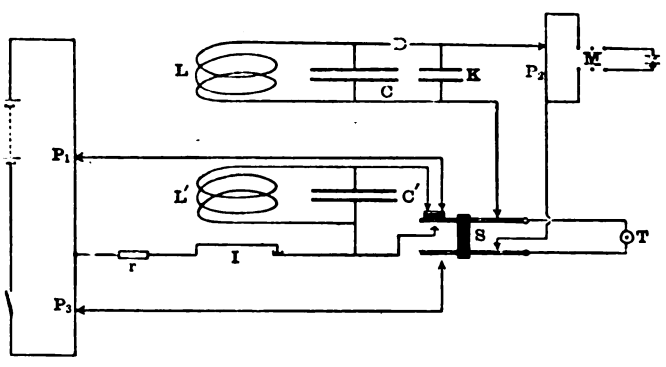

Fig. 1.

amplitude of the order of a few hundredths of an ampere could be excited in this primary; and hence feeble electrical oscillations of calculable magnitude could be excited in the secondary. The amplitude of the oscillatory E.M.F. at the coherer contact, and the energy delivered to the coherer, can be computed from the amplitude of the primary oscillations; but, besides other considerations, the lack of facilities for measuring the small mutual inductance between primary and secondary made another method (described below) of determining the energy seem preferable.

The trains of damped oscillations in the primary were produced by making and breaking a small current running through the primary inductance. In consequence, the coherer yielded a sound in the telephone connected in series. As a general rule, the telephone sound is greater the greater the amplitude of the oscillations in the primary, because the response of the coherer is greater. To measure the response of the coherer, the intensity of the sound was balanced against another sound which was produced in the same telephone by the interruption of an independent source of direct current, which could be switched into the circuit of telephone and interrupter in the place of the coherer. In this way the behaviour of the detector could be quantitatively recorded when the steady current through it, or the oscillatory energy delivered to it, underwent desired variations. The method has enabled me to attain some degree of consistency in measuring the effects of oscillatory voltages as low as $\frac{1}{10}$ volt, and energy transformations of the order of a few thousandths of an erg.

Only one type of coherer has been examined closely. This is a mercury and oxidised iron coherer—a kind I have used for many years, and chosen for these experiments after careful comparison with a number of similar coherers of more modern vogue. As is well known, almost any conductor that can be coated with a closely

adherent, tenacious and very thin film of solid or liquid of not too high resistivity makes a good coherer: for example, oxidised or sulphided copper against any solid conductor; oxidised iron, steel, nickel, tantalum, or any similar metal, against mercury or other conductor are all good.* I have tried also iron-mercury coherers made by the action of organic acids and other reagents on iron. For example, even the graphite (?) films left on a steel knife that has been unwisely used as a fruit-knife make coherers. Amongst all these and others I have found that the best for my present purposes is the coherer made by dipping the end of a carefully oxidised fine iron wire or steel needle into a pool of clean mercury. It is important that the layer of oxide on the wire should be of uniform very small thickness. Seven or eight years ago I found that this can be accomplished very well by heating the wire in a glass tube carrying steam from a boiling flask. The wire should be watched till the film of oxide yields one of those interference colours familiar in the tempering of steel. For instance, a blue film makes a splendid coherer, which works well for a month or two in the open air. Most of the experiments discussed below were carried out on coherers made in this way.

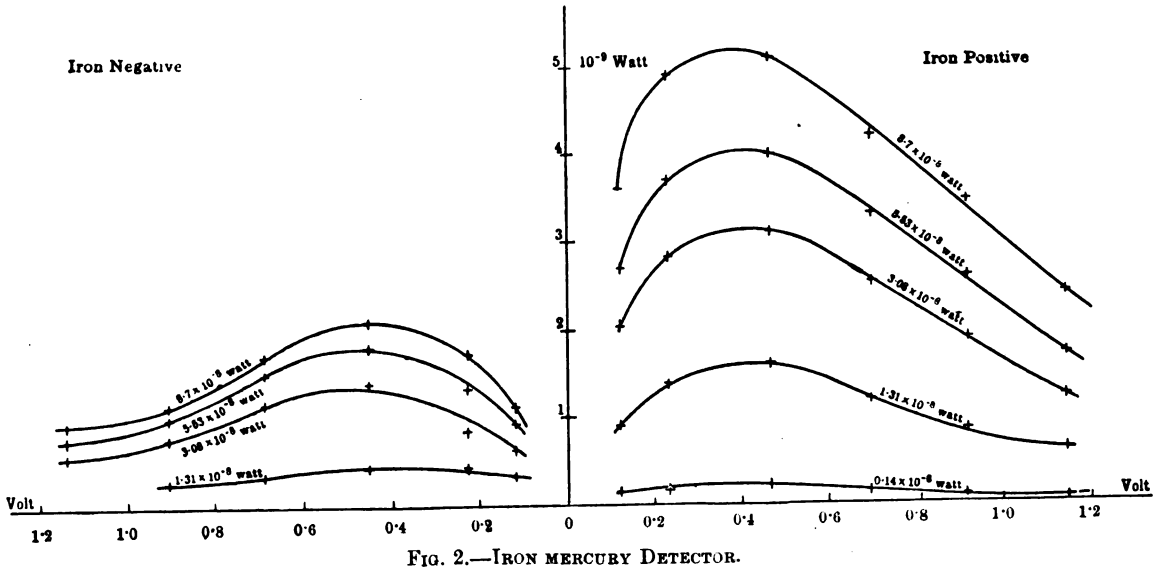

FIG. 2.—IRON MERCURY DETECTOR.

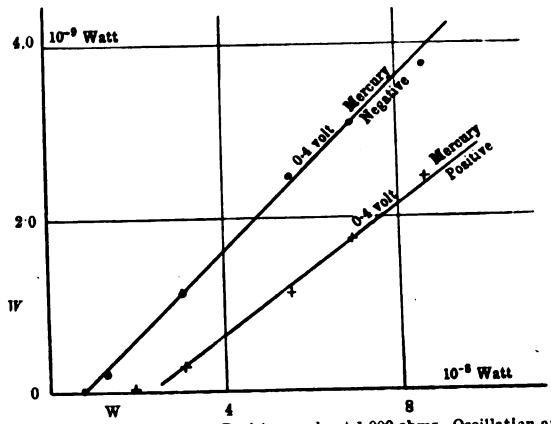
Apparatus.—Fig. 1 is a diagrammatic plan of the apparatus. The primary circuit consists of the coil L′ and condenser C′; the secondary of L and C. The detector D and condenser K are arranged shuntwise to the condenser C. C and C′ are variable condensers of the Marconi pattern. K is an air condenser. L and L′ are coils wound on waxed cardboard tubes. The six-contact key S is designed to throw the telephone T quickly from the detector circuit to the direct-current circuit. In the position of S shown in the diagram the telephone is in series with the detector and part of the potential divider P_2, and at the same time the primary inductance L′ is connected through portion of the potential divider P_1 and the interrupter I. When the key S is depressed the telephone is connected directly through the interrupter I and the potential divider P_3, and the secondary circuits are disconnected. The mutual inductance between primary and secondary can be varied by running L′ along a straight slipway to or from the coil L; but usually the coils were held so that their mutual inductance was a few hundreds of centimetres. The resistance r is an important detail. Its purpose is to prevent the formation of oscillations in L′ at the make of the primary current; calculation (as well as experiment) shows that if r lies within certain limits oscillations occur in L′ at the break only. The amplitude of the oscillations is governed by aid of the potential divider P_1. The frequency of the interrupter I was chosen of the low value 22 per second; thus resonance with the telephone diaphragm was avoided, and the balancing of the sound produced by the detector with that produced by P_3 facilitated. The electrical dimensions of the apparatus were as follows: L′ = 33,700 cm., C′ = 5,020 cm., L = 42,700 cm. C = 3,940 cm., K = 1,210 cm., r = 20 ohms, T = 311 ohms. The mutual inductance between L and L′ ranged from 200 cm. to 2,500 cm. in obtaining the results described below. These sizes were settled upon after many changes, partly because they were practical sizes (wave-length about 820 metres), but chiefly because certain later calculations were made easier.



W = power supplied as oscillations. Resistance about 1,000 ohms. Oscillation amplitude at coherer = 442 × √W volt.

FIG. 3.—IRON-MERCURY DETECTOR.

Details of Method.—In the experiments the primary and secondary were used slightly out of tune. This is very necessary when detectors whose resistance varies are under study; for the variations of a coherer's resistance are quite wide enough to carry the secondary circuit erratically from one side to the other of perfect resonance if the circuits are initially very near that condition, with the result that inconsistent measurements would be inevitable. It is, of course, as easy to deduce formulæ for the mistuned as for the tuned circuits. The expression for x, the current through the detector at break of primary current, is of the form

$$x = le^{-at} + ke^{-mt}\cos(pt+q) + ke^{-bt}\cos(ct+d),$$

where m and p belong to the primary circuit and b and c to the secondary circuit, the coupling being very feeble. The coefficients l, h, k are complicated functions of the electrical dimensions of the circuits. Hence the energy delivered to the detector at a break appears as six terms, of which, with the dimensions adopted, only two are of

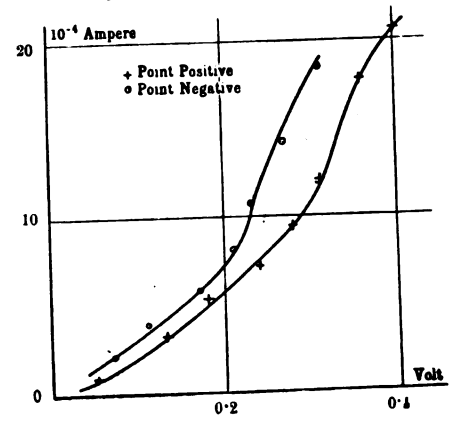


FIG. 4.—IRON-MERCURY DETECTOR, STEADY CURRENT CURVES.

Digitized by Google

numerical importance—namely, $h^2/4m$ and $2lh/m$. The other terms are less than 1 per cent. of the larger of these. Both h and l involve m, the damping factor of the primary, but not prominently. This fact enabled m to be determined easily and with sufficient accuracy. A calibrated thermo-galvanometer with a heater and series resistance totalling 1,000 ohms was put in the usual place of the detector; the mutual inductance between the circuits was increased (but the coupling was still very small), the speed of the interrupter was raised, and heavier primary currents were used than was customary when a detector was in position. Thus a considerable deflection of the thermo-galvanometer was obtained and recorded. Then a short loop of very thin copper wire of known high-frequency resistance was put in series with L″, and the observation repeated. Since the energy received by the thermo-galvanometer is proportional inversely to the resistance of the primary on each occasion, the high-frequency resistance of the coil L′ can be calculated from the observations. The mean of several determinations gave 0·78 ohm. The steady-current resistance was 0·22 ohm.

The power delivered to the detector in the standard conditions of the circuits and primary currents can be computed as just indicated. For accurate results it is necessary to know M, the mutual inductance between primary and secondary, and m, the primary damping factor, very accurately. As neither of these could be determined with the precision desirable, the thermo-galvanometer was invoked to determine the power passing from primary to secondary. In fact, the experiment to determine m, just described, may be taken as determining the factor of transference of power. Similar observations to the above were therefore made with primary currents of different values and with rather high speeds of interruption

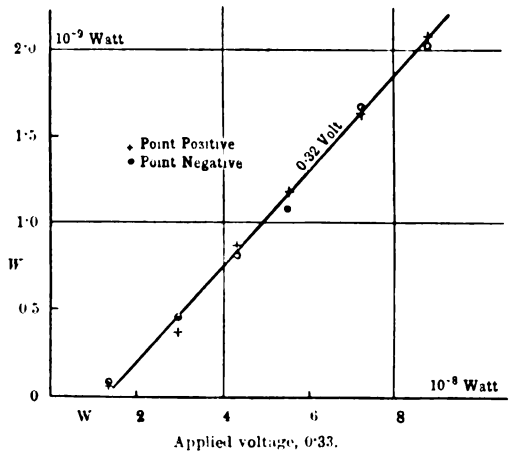

Fig. 5.—Iron Point on Oxidised Iron Plate (light blue film).

(nearly 200 per second), and the fact was established, obvious theoretically, that the power passed to the thermo-galvanometer was proportional to the square of the primary current and to the frequency of interruption. Finally, by observation of the thermo-galvanometer deflection, when a primary current of $\frac{1}{10}$ ampere was interrupted 168 times a second, the result was established that with the primary and secondary in their standard relation a quantity of energy amounting to very approximately $4{\cdot}82 \times 10^{-11}$ joule, or about 0·0005 erg, is passed to a detector of 1,000 ohms resistance at each break of a primary current of 0·01 ampere. This corresponds to a power delivery of 0·01 erg per second when the interrupter is running at the standard frequency. Corresponding figures were obtained for the cases where the detector has different resistances between 100 ohms and 2,000 ohms.

In the actual experiments on detectors two things were chosen for variation, namely, the E.M.F. applied to the detector and the oscillatory energy passed from the primary to the detector. The effect observed was the loudness of the sound in the telephone. The curves of Fig. 2 have as abscissæ the varying external E.M.F. applied to the coherer, and as ordinates the consequent effect in the telephone. Each curve in the diagram is obtained by supplying to the coherer the constant power marked on the curve. The curves in Fig. 3 have as abscissæ the power supplied to the coherer when its applied E.M.F. is unvarying; the ordinates are the effect in the telephone. The telephone effect is plotted as estimated power given by the coherer to the telephone circuit. The numerical connection between the power passed into the telephone circuit and the measured intensity of the sound in the telephone was determined as follows: The thermo-galvanometer was put in the telephone circuit in series with the telephone, and a large primary current was interrupted at the normal rate. The intensity of the loud sound in the telephone was measured by the potential divider, and at the same time a reading of the galvanometer deflection was taken. A resistance was then put in series with the telephone and the galvanometer, and the measurements repeated. These readings give sufficient data to determine the amount of energy being dissipated in the telephone when the intensity of a sound is equal to that due to any assigned length of the potential divider P_3. The measurements thus made show, both sides, that the power delivered by the detector to the thermo-galvanometer and telephone was practically proportional to the square of the length of P_3 required to produce equal sounds in the telephone. It is rather a big extrapolation to extend these results obtained with currents large enough to affect the thermo-galvanometer to currents that give only faint sounds in the telephone; but if we do this, we find that when the intensity of sound produced by a detector is equal to that obtained by interrupting a telephone current of 1 microampere 22 times per second, then the power passed from the detector into the telephone circuit is $4{\cdot}38 \times 10^{-12}$ watt, *i.e.*, $4{\cdot}38 \times 10^{-5}$ erg per second. By the aid of this factor the curves of Fig. 2 and 3 were drawn.

Results.—The most striking outcome of the measurements is embodied in Fig. 3. The curve connecting the power delivered to a coherer as electrical oscillations and the power passed by the coherer to the telephone turns out to be a straight line passing nearly through the origin. The line is different for different values of the steady E.M.F. applied to the detector. The upper curve of Fig. 3 was obtained from a rather insensitive coherer, which happened to have a resistance of about 1,000 ohms at its most sensitive voltage, the iron being positive. The lower curve is one selected under similar considerations with the iron negative. The approximate equation of the former curve is $w = 0{\cdot}024(W - 0{\cdot}9 \times 10^{-8})$, and the latter $w = 0{\cdot}019(W - 2{\cdot}2 \times 10^{-8})$, the unit being a watt. All the other curves that have been obtained with coherers of various construction, resistance, applied E.M.F., are very like these. The more sensitive the coherer the steeper the line, is the only rule that has yet come to light (and in some

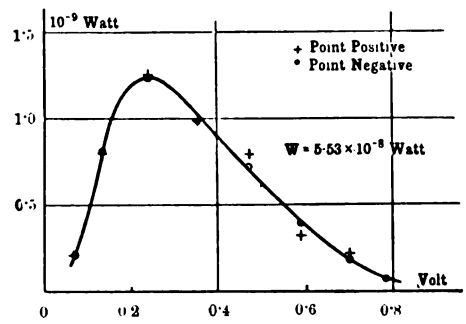

Fig. 6.—Iron Point on Oxidised Iron Plate.

iron-mercury coherers the gradient of the line is 0·06); there is no rule yet proved for the constant term subtracted from W. It may be mentioned again that the absolute value of the multiplier of W in the above equations is rather doubtful, because of the big extrapolation necessary in calibrating the telephone. But doubt on this point does not affect the character of the curves; it affects only their gradient. As written above, the approximate equations for the curves suggest that for a particular detector under invariable conditions there is a fixed wastage of oscillation energy amounting constantly to about one-tenth of an erg per second, however large or small the oscillation energy given to the detector may be. If, however, the equations be written $w + 0{\cdot}022 \times 10^{-8} = 0{\cdot}024W$ and $w + 0{\cdot}042 \times 10^{-8} = 0{\cdot}019W$, the inference is that a small quantity of energy, which is invariable while the detector is undisturbed, is delivered by the detector to the telephone circuit in a form that never makes any proportion of itself manifest as sound. Whatever the cause of this small energy wastage may be, the curves of Fig. 3 show that the coherer must be put amongst those detectors that have been called "integrating" detectors. Thus the coherer is not, as has usually been supposed, a "voltage-operated" detector. As detectors go, it has a very good efficiency (*i.e.*, ratio of energy conversion), but evidently its efficiency falls rapidly as signals get weak.

The curves of Fig. 2 show how the sound heard in the telephone varies with alteration of the P.D. applied to the coherer and telephone in series. Each curve is obtained by submitting the coherer to the fixed excitation whose value in watts is marked on that curve. As the excitation diminishes the maxima accompanying variation of applied voltage becomes less marked. The resistance of the coherer was kept as constant as might be during these experiments, but wide variations of resistance are inevitable. The asymmetry of the coherer under positive and negative voltages shown in these curves obtained by the action of electrical oscillations on the instru-

Digitized by Google

ment is no doubt connected with the similar phenomenon mapped in Fig. 4, where typical steady current curves, plus and minus, are drawn. In these curves the abscissæ are the P.D.s applied at the terminals of the coherer. In both cases the lack of symmetry is due to the use in the coherer of two metals so different as iron and mercury. In order to examine whether this asymmetry was responsible for the failure of the curves of Fig. 3 to pass through the origin, a new series of experiments on a different form of iron-oxide coherer was undertaken.

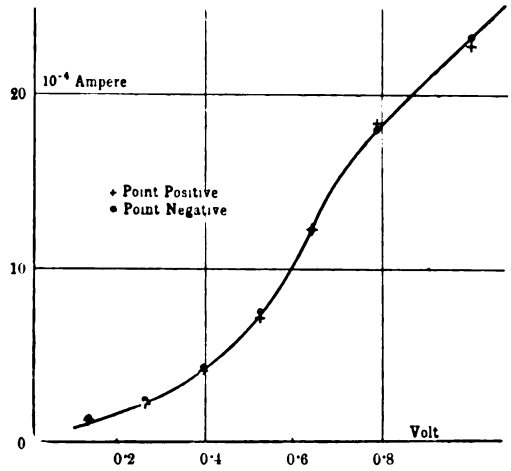

FIG. 7.—IRON POINT ON OXIDISED IRON PLATE, STEADY CURRENT CURVES.

Additional Experiments.—A coherer was made by heating a polished iron plate in air till rings of colour round the small heated area indicated that the plate was covered with a thin film of oxide. The end of a clean piece of iron wire was so held as to press on the plate at any desired place with a constant force. The plate was made one terminal of the coherer and the wire the other terminal, and this coherer was examined in precisely the same way as the others. A typical series of measurements is set forth in Figs. 5 and 6. The curve connecting the energy given to the coherer and the energy passed to the telephone is again a straight line passing

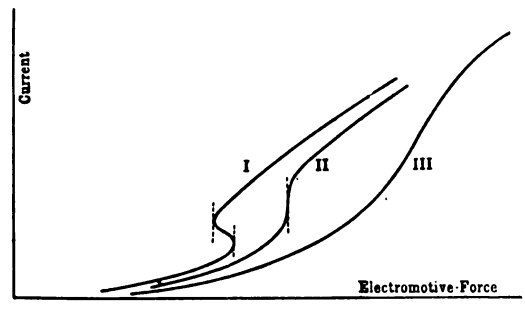

FIG. 8.—IDEAL CURVES SUGGESTED BY THEORY.

some distance from the origin. The equation of the curve is $w=0{\cdot}028(W-1{\cdot}4\times10^{-8})$. The curve is the same whether current passes from point to plate or in the opposite direction, which clearly indicates that the asymmetry of the other curves was due solely to the use of two metals. The curves connecting applied voltage and steady current for these iron-point iron-plate coherers are also the same whatever the direction of the current. Fig. 7 shows such a curve, which has been selected from a large number as typical.

(To be concluded.)

Telephone Improvements at Panama.—According to the "Electrical World," the telephone exchanges at Culebra and Paraiso, in the Canal Zone, are to be consolidated with the Empire exchange as soon as the work of installing new equipment at Empire is completed. The "central" at Paraiso has been abolished, and the stations served by it were temporarily connected with the Culebra exchange. The consolidation is designed to increase the efficiency of the service by centring the operations at a point where they can be given closer supervision. A saving in operating expenses will also be effected. The new equipment at Empire will include a modern common-battery two-section switchboard to serve 400 stations.

GAS ENGINES IN CITY RAILWAY AND LIGHTING SERVICE.*

BY E. D. LATTA, JUN.

Summary.—The author first describes the plant in the small, but thoroughly equipped, central station of the Charlotte Electric Railway Co., in which gas engines are used for prime movers, and current is supplied for street railway purposes, electric lighting and motors in small units. He also gives from the daily operating reports some figures from which can be formed an idea of the reliability, efficiency and adaptability of the plant. He sets forth data on the subject of producer gas manufacture, finally offering a few remarks on the adaptability and advisability of gas engines for certain kinds of work.

The period covered by this Paper, viz., 12 months, dates from January 1, 1909, when the plant had been in operation for about six months, and could be considered as being fairly well under way.

The engine room equipment consists of two 810 B.H.P. horizontal twin-tandem double-acting four-stroke cycle gas engines and one 60 H.P. single tandem exciter engine. The 540 kw. three-phase 60-cycle 2,300-volt alternators are direct and rigidly coupled to the crank shafts of the main engines, and a 40 kw. direct-current generator is direct-connected to the exciter engine. In addition to this apparatus there is an induction motor-driven exciter set of the same capacity as the engine exciter, a 300 kw. and a 500 kw. rotary converter, and the usual switchboard equipment.

The producer apparatus is contained in a building about 100 ft. from the power house, and consists of two 1,000 H.P. units of twin generator down-draught producers, having a continuous overload capacity of 50 per cent. Each unit consists of two 9 ft. generators, 16 ft. high, having a fuel space 7 ft. in diameter by 8 ft. high above the grate bars, which are of arched fire-clay tile. The generators are connected at the bottom by openings, lined with firebrick, containing water-cooled gate valves, to an economiser or vertical boiler of 100 H.P. rating. From the top of the boilers a 16 in. pipe leads to the bottom of the wet scrubber and from the top of the wet scrubber to the exhauster, or through a by-pass around the exhauster to the dry scrubber. A 60,000 cubic ft. holder receives the gas from the producers and delivers it to the engines. The flywheels of the engines are 16 ft. in diameter and weigh 34,000 lb. Each engine occupies a floor space of 18 ft. by 44 ft. All parts of the engine that come in contact with the hot gases are water-jacketed, including cylinders, pistons, piston rods, mixing chamber, valves and valve seats, and the exhaust pipe down to the floor level. The jacket water from the various parts of the engine empties from separate pipes into open funnels, which enables the operator to determine at all times the temperature of the different parts of the engine. The ignition is low tension make-and-break, with two igniters to each end of cylinder. The ignition current is supplied by one of three batteries of five cells each, and requires about 10 volts. The governors are of the Jahns type, in which the centrifugal force of the weights revolving in a horizontal plane is resisted by the direct pressure of coiled springs, the weights turning on rollers in a constant oil bath which practically eliminates friction. The governor is driven by a belt from the camshaft, and governing is done with a uniform mixture. A plunger in the face of the flywheel works in and out radially against a coiled spring. In case of excessive speed of the flywheel, centrifugal force drives the plunger out beyond its normal position and opens a switch in the igniter circuit, thus shutting down the engine and preventing racing in case of the governor belt breaking or the governor otherwise losing control of the engine. This device is tested at regular intervals by depressing the governor, and is found invariably to operate within five or six revolutions above normal speed.

The problem of piston packing, which for many years was one of the greatest difficulties in the way of building double-acting engines, has been solved in a fairly satisfactory manner by the use of metallic packing contained in packing cases. The packing cases each contain five rings of special cast-iron made in segments, with overlapping joints, the segments being held in place against the piston rod by a $\frac{3}{16}$ in. garter spring drawn around the circumference. The packing case is bolted to the cylinder head by means of a flange, between which and the cylinder head is a ground joint. About once a month each packing case is removed and supplied with clean packing. The packing removed is then thoroughly cleaned when convenient and put aside for use at another time. If a high grade cylinder oil is used and the packing is regularly cleaned, the troubles from this source are practically eliminated.

During the summer months about 15 gallons of water, at an initial

* Abstract of a Paper read before the American Institute of Electrical Engineers.

Digitized by Google

temperature of 80°F., are required per horse-power-hour for cooling, the temperature of discharge being about 120 deg. During the winter months 10 gallons of water per horse-power-hour at 60 deg. are sufficient, and are discharged at about 100 deg. The difference in the amount of water required in summer and winter is apparently due to the fact that the heat lost by radiation is much greater in winter. The jacket water after being discharged from the engine flows by gravity to a hot well of the cooling system, from which it is drawn by an electrically-driven centrifugal pump of 50,000 gallons per hour capacity, against 15 lb. pressure, and forced through sprays into a basin in the middle of which is a cold well. From the cold well it is taken by a two-stage turbine pump of 15,000 gallons per hour capacity against 30 lb. pressure, and returned to the engine. These pumps are driven by the same motor. As the capacity of the single-stage or hot-well pump is three times as great as that of the cold-well pump it follows that an excess of water is sprayed into the basin over that taken out of the cold well; this excess water overflows and returns to the hot well where it is again pumped through the sprays. In this way all the water passes through the sprays three times to each time it is used in the engine and ample cooling is obtained, the water in the cold well being reduced to a temperature slightly below that of the atmosphere. The loss in water by evaporation to attain this degree of cooling is about 10 per cent.

There are three classes of disturbances that take place infrequently in these engines, as is the case with all gas engines, viz., pre-ignition, back-fires and muffler explosions. The first of these is caused by the use of gas over-rich in hydrogen, which ignites very readily under high compression without other application of heat; also by particles of carbon or other solid matter which become lodged in the cylinder and become incandescent under the temperature of compression, or when any of the water-cooled parts of the engine are insufficiently cooled by using too little water, or water at too high temperature. A back-fire occurs when the gas admitted to the cylinder is ignited on the suction stroke, but can also be caused by a leaky inlet valve, in which case the gas in the inlet pipe is ignited during the explosion stroke. Ordinarily a back-fire is caused when gas of a too lean nature is used, so that the gas burns very slowly and continues to burn in the exhaust stroke. A part of the gas still burning in the clearance space ignites the incoming charge. Also if there are any pockets or small passages, such as the water-cooled pipe leading to the indicator cock, the gas in the passage or pocket is cooled to a point where it does not ignite readily. It becomes heated and ignites in the latter part of the pressure stroke, and continues to burn until the succeeding intake stroke when the incoming charge is ignited. The result of a back-fire is only the loss of the next power stroke, and usually a mis-fire at the second succeeding power stroke caused by the burning gas blowing back into the intake pipe and fouling the gas contained in it. The disturbance caused by pre-ignitions and back-fires is only momentary, and even when the engines are operating in parallel very little effect can be noticed. A muffler explosion is caused after a mis-fire, when an unburned charge of gas and air passes into the exhaust pipe and is ignited by the exhaust from the power stroke of another cylinder. It has no effect upon the operation of the engine, but makes a noise similar to that of a pre-ignition or back-fire.

Improper action of a gas engine is not shown nearly so clearly by the indicator card as it is in the case of a steam engine. For instance, the exhaust valve of a gas engine might be leaking and the only indication of the trouble would be low compression, yet the low compression might be caused also by badly worn piston rings or by packing in bad condition. The principal value of the indicator card is in adjusting the proportion of air and gas to give the most effective mixture, and for properly timing the ignition. To adjust the mixture it is desirable to put a steady load upon the engine, preferably that produced by a water box, and then indicate the engine and adjust the mixing valve until the card shows the maximum explosion pressure for a given compression, which is the condition existing when sufficient air for complete combustion is admitted with the gas, without excess.

Plant Performance.—Under this head, considering the class of service, reliability is of paramount importance. Details of the shut downs during the year are given by the author, and total 2 hours 45 minutes, the plant operating 24 hours per day. The failures were twice due to exciter, twice to suction of engine drawing water from the gasometer into gas main, shutting off gas supply and once each to belt of oil pump breaking, earthing on ignition wiring, operation of safety stop valve and unusual overload.

Second in importance to reliability are speed regulation and ability to operate successfully in parallel. The manufacturers guaranteed that from 25 per cent. to full-load the engine would govern within a maximum variation of 2 per cent. This condition is met as regards the mean speed on steady loads. When, however, a heavy load is suddenly thrown on the engine, or removed from it, a momentary swing of not exceeding 2 per cent. below or above mean speed for the given load occurs, which is due to over-reaching of the governor. While this swing in speed is not excessive, and is found to an equal or even greater extent in high-class reciprocating steam engines, it is rather remarkable that it is not far worse than the above figure in a four-cycle gas engine; for at the moment the load on the engine is changing, the governor has no control whatever upon the charge of gas next to be ignited.

It is generally supposed that the turning moment or angular velocity of a gas engine is uneven and characterised by periodic variations with each impulse, due to the fact that the initial cylinder pressures are extremely high as compared with those of steam engines. This would no doubt be the case with a single-tandem four-cycle gas engine, but with the twin-tandem engines having four double-acting cylinders eight impulses are given to the flywheel in two revolutions or one complete cycle. Therefore, as the cranks of the two sides are quartering, an impulse is imparted to the flywheel every 90 deg., or two impulses per stroke. The impulses thus overlapping tend to smooth out the variations that otherwise would occur, and permit of a far lighter flywheel than could be used with a single-tandem engine. The lighter flywheel is less sluggish and consequently promotes good parallel operation, but it is not too light to afford sufficient inertia practically to absorb the variations in crank effort

We have been convinced of the correctness of this statement by observing the behaviour of the alternators at various times when they were running in synchronism, with the engine cranks in almost every possible relation. No difference can be discerned in the action of the switchboard instruments, whether the cranks are in step or in any other possible position.

While the parallel operation of this engine would not be considered good in comparison with steam turbines operating at high speed, with alternators having from two to four field poles, it nevertheless compares favourably with the best type of reciprocating steam engines with alternators having the same number of field poles, viz., 60, which, of course, means that the variations in electrical degrees will be 30 times as great per degree of angular variation as would be the case in a turbine of the same capacity operating at 3,600 revs. per min. The temperatures of the alternators above room temperatures, so far as can be observed with the constantly varying load, do not indicate an excessive synchronising current, and there has never been any tendency on the part of the synchronous converters to fall out of step.

Cost of Operation and Repairs.—The load factor is poor, due principally to two conditions—first, the prevailing load for 20 hours per day is easily within the range of one unit, but the wide limits of variation make it necessary to operate the second engine on an average 10 hours per day; and second, from 12 o'clock night until 6 a.m one engine operates on practically no load at all. We estimate that with an increase in the load factor of 25 per cent. the additional output could be produced for an amount not exceeding 10 per cent. of the present cost. In the matter of cost of repairs, also, we expect a reduction rather than an increase in the near future. The largest item in the total cost of repair parts is the cost of an entire new equipment of exhaust valves, which amounts to about half of the total. These exhaust valves were put in, not on account of wear and tear, or breakage, but on account of the inferior design of the original ones. Four pistons have been taken out and fitted with new rings, the original rings having become broken when water leaks occurred in the cylinders due to defects in the castings of the piston water compartments. Broken rings almost invariably result from water leaks in a cylinder. In this case, new parts were furnished by the manufacturers without charge, and the labour was furnished principally from the operating force.

The least serious trouble that has been encountered, but one of the most annoying, on account of its occurring at most inopportune times, is the breaking on six occasions of the wedge adjusting bolts in either the crank or cross-head bearings.

The figures for the whole year are as follows: Units 3,355,907, engine-hours 12,403, pounds of coal 6,444,281, load factor 0·45. The load factor is given by $\frac{\text{Output}}{\text{Engine hours} \times \text{capacity of one engine}}$.

In addition to the coal, 260,292 lb. of coke were used in starting producers, of which amount 122,371 lb. were reclaimed, leaving the total net amount used 137,921 lb., equal in cost to 192,000 lb. of coal. The total coal consumption, therefore, is equivalent to 1·97 lb. per kilowatt-hour over the whole year.

Interest, depreciation, taxes, &c., are not included, as buildings, producers, &c., are provided for three units, although only two are installed.

Producer Operation.—In starting a producer the generators are charged to a depth of 5 ft. with 72-hour coke, requiring about 6,000 lb. to each generator, or a total of 12,000 lb. The exhauster is then started and the coke ignited. The gas made during the first 40 minutes is too inferior to be of any use in the engine, and it is therefore blown out and wasted. As the coke in the generators burns and becomes hot, coal is charged at the top in small quantities and at frequent intervals. If coal is charged too rapidly, particularly in the early stages of the fire, it tends to coke, with the result that the draught will be unequally distributed over the fuel bed, finding its way down through holes and localising the heat to such an extent that the excessive temperature causes clinker to form, thus reducing the capacity of the generator and shortening by several days the time that the set can be run without shutting down for cleaning. When the fuel bed has attained a sufficiently high temperature the gas is admitted to the holder. Steam is introduced at the top of the charging doors and, together with the air, is drawn in by the exhauster, passing down through the generator, forming a mixed gas.

At intervals of 20 to 30 minutes, up and down steam runs are made in the generators in the following manner. The by-pass around the exhauster is opened, the charging doors of the generators closed, and steam is admitted beneath the grate bars of one generator, the gate valve of which is closed, for about 30 seconds. This steam passes up through the generator, moistens the ash, breaks up the fuel bed and cools the fuel at the point where clinker is forming, and which is not reached by the top steam before decomposition takes place. This steam leaves the generator through a connection at the top, passing over into the top of the second generator, down through the fuel bed and out through the other apparatus to the holder as a fixed gas. The direction of the steam is reversed on the next run, so that the generators are alternately treated in the same manner.

The hot gas leaves the generators at a temperature of about 1,200°C., and passes out through a brick-lined nozzle and water-cooled gate valve into the lower compartment of the vertical economiser, which is also brick-lined. A large part of the sensible heat of the gas is given off and goes to make steam which is used in the generators and for running the exhauster. From the top of the economiser the gas passes, at a reduced temperature, to the bottom of the wet scrubber where it is water sealed, and passing up through the wet scrubber, it works its way through several layers of coke over which water is sprayed from above. During its passage through the coke and water most of the dust and lampblack in the gas is removed, and its temperature is reduced to that of the atmosphere. In the top of the wet scrubber a thick layer of excelsior removes part of the moisture and most of the remaining lampblack. From the wet scrubber the gas goes through the exhauster, then to the dry scrubber, where two more layers of excelsior throughly dry it, thence it passes to the holder, a clean, dry, cool gas. It is very important that the gas should be reduced to atmospheric temperature in the wet scrubber by the use of a sufficient amount of cool water. About 4 to 6 gallons per horse-power-hour is required, depending upon the temperature of the water and that of the atmosphere.

The use of a large holder, such as the one installed in this plant (60,000 cubic ft.) is of great value in operation. It takes up the variations in load and allows the producer to be operated at an even rate; also, if the gas varies in quality over short intervals, which is unavoidable, the gases above and below the mean value are thoroughly mixed and a gas of uniform quality is supplied to the engines.

It may be of interest to describe a rather serious difficulty which was encountered, and the way in which it was remedied. A short time after the plant was put into operation, it was found that some of the tubes of the economisers were leaking. The tubes were rolled and the leaks stopped, but in a short time they were found to be leaking again. They were again rolled, but continued to leak, and when finally too thin to be any longer rolled they were taken out and replaced with new tubes. The old tubes when taken out were cut into sections and split open, and it was found that they were badly pited throughout their entire length, although the pitting was worse at the upper end; weighing the tubes disclosed the fact that they had lost nearly 25 per cent. of their original weight. After much surmising, the cause of the pitting of these tubes is believed to be as follows: In the usual design of plants of this kind, with two or more sets of apparatus, the various sets are absolutely independent of each other as far as the wet scrubbers, and as the gas is water-sealed in the wet scrubbers it is impossible for gas from one set to pass over into another. In this plant, however, in order to increase the flexibility of operation, the two economisers were connected together at the top by a horizontal header, and each one was cut off from the header by a gate valve. These gate valves coming in contact with gas at fairly high temperature expand and contract, and cannot be kept perfectly tight during steam runs. When the generators were under pressure leakage of these valves permitted hot gas to pass from the economiser in operation to the one shut down, and after passing down through this economiser to escape through the open generators. It was found that the economiser not in use sweated profusely on account of the difference in temperature of the room and the water in the economiser, keeping the tubes continually wet. This moisture, combining with the hot gas leaking through the apparatus, undoubtedly formed a strong acid and attacked the tubes. Since arriving at this conclusion, each time a producer is shut down the gates of the valves are thoroughly cleaned, the tubes are cleaned with a wire brush, the tube ends and tube sheet are painted with one coat of graphite paint, and the manholes at top and bottom of the economisers are left open, so that a circulation of air prevents sweating. Since adopting these measures, there have been no more leaky tubes, and it is believed that the trouble has been effectually remedied.

At another time an annoying occurrence was the development of numerous hot spots on the shells of the generators; these hot spots were caused by defects in the linings. It is found to be an advantage after cleaning a generator to wash the surface of the brick exposed to the fuel with fire clay grout, as the grout tends to form a cleavage plane between clinker and brick and greatly facilitates its removal. When cleaning the generators, it is not desirable to remove all the clinker, for in doing so a part of the brick would be chipped off each time, and greatly reduce the life of the lining. About 1 in. or 2 in. of clinker adhering to the brick is allowed to remain, and this coating affords great protection to the surface of the lining.

The author finally gives the theory of producer gas manufacture and combustion. He also questions whether the gas engine is adapted to the conditions of operation described above, unless in connection with a storage battery.

THE ELEMENTARY THEORY OF THE QUADRANT ELECTROMETER.

BY R. BEATTIE, D.SC.

Summary.—The author gives a simple proof of the theory of the quadrant electrometer. He also discusses its sensibility characteristics, and compares them with those of an alternate current moving coil galvanometer.

As is well known, the quadrant electrometer does not always obey the rules laid down for it in the text-books. According to the theory usually given, the sensibility is proportional to $\{V-(v_1+v_2)/2\}$, where V is the potential of the needle and v_1, v_2 are the potentials of the quadrants. Thus, with v_1 and v_2 small, the sensibility should be proportional to V. In point of fact, however, as was first shown by Hopkinson,* the sensibility generally reaches a well-defined maximum as the potential of the needle is raised. Much has been written with a view to elucidate this point, the chief Papers dealing with the subject being those of Gouy,† Ayrton, Perry and Sumpner,‡ Walker,§ and Orlich,‖ and in these Papers the development of a strict and full mathematical theory of the electrometer may be traced, and a satisfactory explanation of the peculiarity just mentioned may be found.

The purpose of the present Note is not to add anything to

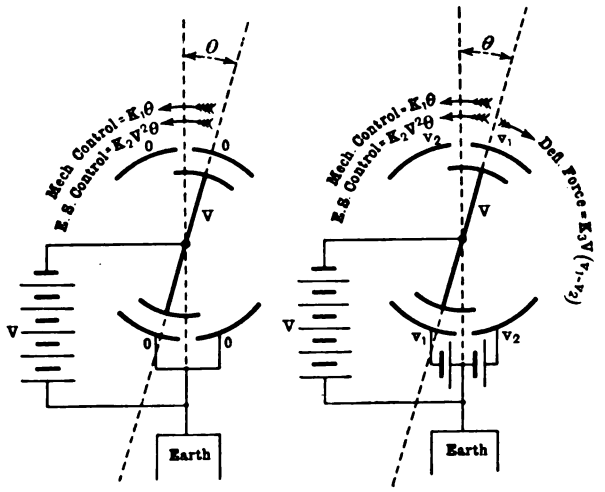
this theory, but rather to reduce it as far as possible to its purely physical elements and present it in its most elementary form. It has been felt that a simple explanation on these lines of the characteristics of the electrometer would be welcomed by many workers with the instrument who have neither the time nor the inclination to follow the mathematical arguments of the more complete theory.

The customary point of departure in establishing the theory of the electrometer is to write down an expression for the energy of the system in terms of the potentials and the position of the needle. From this, by differentiation, the value of the force acting on the needle is then obtained. It is safer,* however, and more direct, to start with the forces and equate, say, the controlling and deflecting couples acting on the needle; and this is the plan adopted in the following discussion. It is necessary, however, to be quite clear at the outset as to what is meant by the controlling couple and what by the deflecting couple. To prevent any misconception on this point, it may be advisable, therefore, to explain that the controlling couple on the needle in any given position is understood to mean the total couple on the needle from all causes when it is charged to its working potential V, the quadrants being at the same time earth-connected. The deflecting couple is the additional couple which comes on the needle when the quadrants are raised from zero potential to potentials v_1, v_2, the difference between which it is desired to measure.

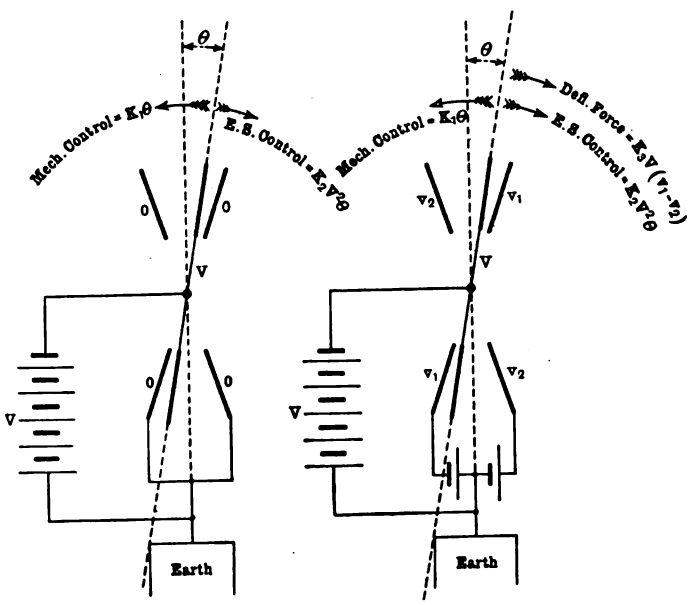


(a) Needle under controlling forces. (b) Needle under controlling and deflecting forces.

FIG. 1.—QUADRANT ELECTROMETER (POSITIVE ELECTROSTATIC CONTROL).

It should, further, be explained that in what immediately follows only a special case is considered—that of a symmetrical electrometer used to measure small potential differences, the needle being at a high potential, V, and the quadrants at potentials v_1, v_2 not far removed from zero. The deflections are also supposed to be small.

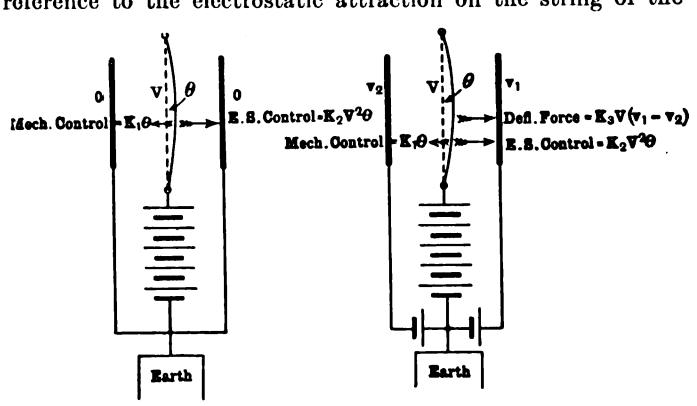
Controlling Couple on the Needle.—Any departure of the electrometer from the ordinary law is entirely accounted for by the fact that the controlling couple on the needle is not single (*i.e.*, is not due to the suspension alone, as is generally supposed), but is double, and arises partly from the suspension and partly from electrical causes. This will at once be clear on reference to Fig. 1, which represents diagrammatically an electrometer with its needle charged to potential V and its quadrants earth-connected. In an electrometer of this type, when the needle is displaced from its symmetrical position by a small angle θ, there are obviously two forces brought into play, both tending to bring it back again. There is, in the first place, the mechanical controlling couple due to the suspension. Being proportional to θ, we may represent this couple by $K_1\theta$, where K_1 is a constant. Next there is the electrostatic attraction between the needle and the quadrants, which, of itself, even if the needle were freely suspended, would suffice to pull it back to the symmetrical position. The restoring couple due to this latter cause—the "electrostatic control," as it may be called—is proportional to V^2 and to θ, and may therefore be represented by $K_2V^2\theta$, where K_2 is a constant. Thus the total controlling couple is $(K_1+K_2V^2)\theta$.



(a) Needle under controlling forces. (b) Needle under controlling and deflecting forces.

FIG. 2.—QUADRANT ELECTROMETER (NEGATIVE ELECTROSTATIC CONTROL).

We have considered a case where the electrostatic control, since it acts in the same sense as the mechanical control, must be reckoned positive. But cases may arise where the electrostatic control acts against the mechanical control, and must, accordingly, be reckoned negative. Evidently this is so in Fig. 2. Here the resultant electrostatic attraction brought into play by any displacement of the needle acts in the direction of that displacement; and the same holds good with reference to the electrostatic attraction on the string of the



(a) String under controlling forces. (b) String under controlling and deflecting forces.

FIG. 3.—STRING ELECTROMETER (NEGATIVE ELECTROSTATIC CONTROL).

string electrometer represented in Fig. 3. In both these cases the electrostatic control must be regarded as negative.

Electrometers can thus be classified into (1) those which possess positive electrostatic control, and (2) those which possess negative electrostatic control. In general, therefore, the total controlling couple on the needle will be represented by $(K_1 \pm K_2V^2)\theta$, the positive or negative sign being taken according as the electrostatic control is positive or negative.

Deflecting Couple on Needle.—Whenever an electrometer with its needle at potential V has the potentials of its quad-

* It is safer for this reason: If we express the energy of the system in the form $(A+B\theta+C\theta^2+D\theta^3+\&c.)$, where θ is the (small) deflection of the needle, and A, B, C, &c., are functions of the potentials, then we have to decide how many terms of the series it is necessary to retain. If we decide to retain two terms and then differentiate, we obtain one result; but if we differentiate first, and then decide to retain two terms, the result may be very different. It is really through omitting to retain a sufficient number of terms in the energy expression that Maxwell's proof ("Elec. and Mag.," Vol. I., §219) fails to disclose the now well-known peculiarities of the electrometer. In dealing with force expressions instead of energy expressions the liability to such an oversight is much less.

Digitized by Google

rants raised from zero to v_1, v_2 respectively, the needle experiences a couple tending to deflect it. If v_1, v_2 are small compared with V, this deflecting couple will, for a given position of the needle, be proportional to $V(v_1-v_2)$, but will vary with the position. Provided the resulting deflection is small, we can always represent the deflecting couple as a function of θ by an expression of the form

$$K_3V(v_1-v_2)(1+a\theta+b\theta^2+c\theta^3+\&c.),$$

where K_3, a, b, c, &c., are constants. But from considerations of symmetry the electrostatic deflecting force must have the same numerical value when (v_1-v_2) and θ are simultaneously reversed. Hence all the terms in the above expression which contain odd powers of θ must vanish, leaving only terms involving the square and higher even powers. These we may neglect and take $K_3V(v_1-v_2)$ as a sufficiently exact expression for the deflecting couple.

The Sensibility.—By equating the deflecting and controlling couples as just determined we get

$$(K_1 \pm K_2V^2)\theta = K_3V(v_1-v_2)$$

or

$$\theta = \frac{K_3V}{K_1 \pm K_2V^2}(v_1-v_2).$$

For the particular case considered, this is the same result as that arrived at, though in a less direct manner, by the more complete theory. It shows that the sensibility of an electrometer is proportional to $K_3V/(K_1 \pm K_2V^2)$. Thus in electrometers with positive electrostatic control (like the ordinary quadrant electrometer) the sensibility reaches a maximum when $K_2V^2=K_1$—that is to say, when the potential of the needle is such that the electrostatic control is equal to the mechanical control. A typical sensibility curve for this type is shown in the lower curve of Fig. 4.

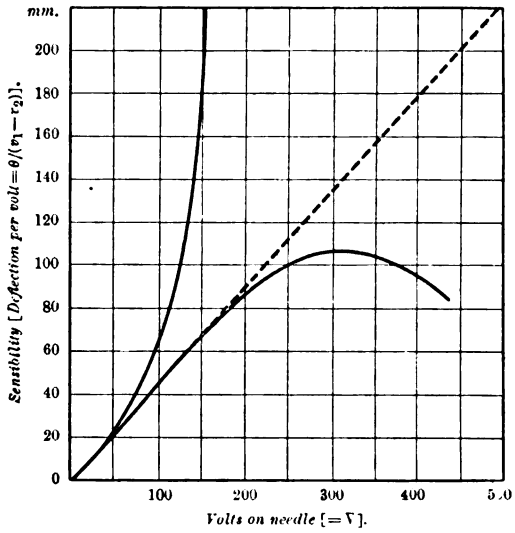


Fig. 4.—Characteristics of Quadrant Electrometer.

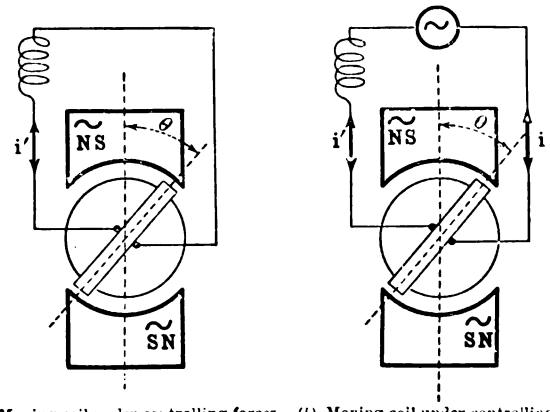
On the other hand, it is seen that in electrometers with negative electrostatic control (like the string electrometer) the sensibility becomes infinite when $K_2V^2=K_1$—that is to say, when the potential of the needle is such that the electrostatic control is equal to the mechanical control. If V exceeds this critical value the instrument is unstable. A typical sensibility curve for this type is shown in the upper curve of Fig. 4.

For any given electrometer there is thus a definite critical potential of the needle which corresponds either to maximum sensibility or to instability according as the electrostatic control is positive or negative. Theoretically it should be possible to construct an electrometer with zero electrostatic control. The instrument would then obey the ordinary law and would have a straight-line characteristic like the dotted line of Fig. 4. Practically it has been shown to be feasible to construct an electrometer in which the sensibility is proportional to V over a very wide range,* but ultimately such an instrument would probably reach either maximum sensibility or instability if only the potential of the needle were raised high enough.

Comparison of the Electrometer with the Moving-coil Alternating-current Galvanometer.—It may be pointed out in support of the idea of a double control which has been made use of to deduce the properties of the electrometer, that the moving-coil alternating-current galvanometer, though entirely different in construction and function, yet possess characteristics similar to those of the electrometer. This parallelism between two instruments so essentially different arises from the existence in each of a double control on its moving system—partly mechanical, partly electrical. The conditions in the alternating-current galvanometer are, however, more easily understood, there being no difficulty in distinguishing the electrical controlling forces from the electrical deflecting forces, whereas in the electrometer the electrical controlling and the electrical deflecting forces are liable to be confused.

In an alternating-current moving-coil galvanometer when the coil, suspended in an alternating magnetic field of strength H, is deflected by an angle θ, as in Fig. 5, there are two couples acting on it. One is due to the mechanical control and may be represented by $K_1\theta$; the other arises from the alternating current i' induced in the coil as a result of the alternating flux which traverses it in its deflected position. The action of the field H on this current produces an electromagnetic control which is proportional to H^2 and to θ, and may therefore be represented by $K_2H^2\theta$. This electromagnetic control may be positive or negative according to circumstances. If there is an inductance in the coil circuit the electromagnetic control is positive; if the inductance is replaced by a capacity it becomes negative. The total control may therefore be written

$$(K_1 \pm K_2H^2)\theta.$$



(a) Moving coil under controlling forces. (b) Moving coil under controlling and deflecting forces.

Fig. 5.—Moving-coil Alternating-current Galvanometer with Positive Electromagnetic Control.

When an alternating current, i, is passed through the coil from an external source, a deflecting couple, K_3Hi, is produced, so that the final position taken up by the coil is

$$\theta = \frac{K_3H}{K_1 \pm K_2H^2} \cdot i.$$

The sensibility of the galvanometer is thus $K_3H/(K_1 \pm K_2H^2)$. It therefore varies with the field strength H in exactly the same way as the sensibility of the electrometer varies with the potential V of the needle.

In pursuance of the analogy it may be noted that just as in the galvanometer the electromagnetic controlling couple on the coil arises from the current induced in it by the field, and the deflecting couple from the current injected into it by an external source, so in the electrometer the electrostatic controlling couple is due to the charges induced on the quadrants by the charge given to the needle, and the deflecting couple to the charges given to the quadrants by some external source.

The Sign of the Electrostatic Control.—Short of actually determining the sensibility curves, the nature of the electrostatic control in an electrometer can be arrived at in several ways. For example, if the periodic time of the needle is found to decrease when the needle is charged, the electrostatic control must be positive ; if the periodic time increases, the electrostatic control must be negative.

In general the sign of the electrostatic control is at once obvious from the construction of the instrument. In doubtful cases a consideration of the changes in the electrostatic field which result from a displacement of the needle will often assist materially in fixing the sign. For instance, with a needle completely boxed in, as in Fig. 6A, and free to move parallel to itself, the only electrostatic lines effective in producing motion are those which form the " fringes " at the edges of the needle. If the needle is displaced from its central position, the number of lines leaving the advancing edge must increase, owing to the edge approaching the side S of the box ; for a similar reason the number of lines leaving the retreating edge must decrease. On the whole the resultant force on the needle due to electrostatic causes is in the direction of the displacement, and the electrostatic control is therefore negative.

Again, in the arrangement of Fig. 6B, with a needle between parallel plates which are separated by very narrow gaps, the electrostatic forces on the needle tending to displace it parallel

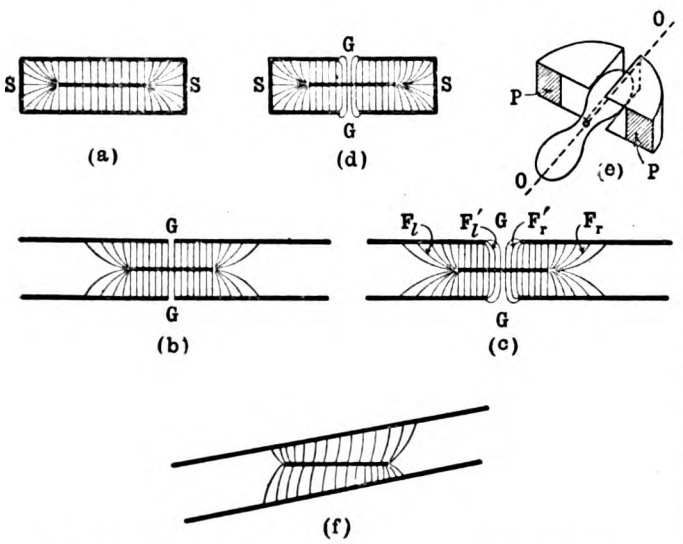

FIG. 6.—ILLUSTRATING METHOD OF DETERMINING SIGN OF ELECTROSTATIC CONTROL.

to itself are entirely the result of the fringes at the edges. If the gap G between the plates is very narrow, the fringes from the two edges will be similar in whatever position the needle may be placed, and will therefore always exert equal and opposite pulls. In this case the electrostatic control is zero.

But if the gap G between the plates is wide (Fig. 6C), we have fringes not only at the edges (F_l and F_r), but also at the gap (F'_l and F'_r). If the needle is displaced to the right the fringes F_l and F'_l are brought nearer together, and the lines in F_l are distorted in such a way as to exert a greater pull. At the same time the fringes F_r and F'_r are separated, and, as a result, the pull of the lines in F_r decreases. Thus the electrostatic forces brought into play oppose the displacement, or the electrostatic control is positive. This explanation is, of course, only a rough one, but it helps to make clear how the positive electrostatic control in the ordinary quadrant electrometer arises, and how it depends upon the width of the gap between the quadrants. Other things being the same, the effect of the gaps is obviously less the further they are removed horizontally from the sides of the needle.*

Such methods are not infallible, however, and often it may be impossible to predict the sign of the electrostatic control with certainty. Fig. 6D is a case in point. Here, if the sides S are far removed from the needle, the electrostatic control arises from the gaps G solely, and must therefore be positive. If, on the other hand, the sides are close up to the needle, the effect of the gap is relatively small, and the control becomes negative, as in Fig. 6A. But, except in these extreme cases, it is impossible to say whether the positive or negative control has the upper hand, and whether the resultant control is positive, negative or zero. This example serves to illustrate how readily a positive control may be converted into a negative by a simple structural alteration. In an ordinary quadrant electrometer a reversal in the sign of the electrostatic control may be effected by attaching plates PP, Fig. 6E, to the quadrants. These play the part of the sides SS of the box in Fig. 6D. and usually cause the electrostatic control to change from positive to negative, with a corresponding change in the sensibility characteristic.

Another way in which a negative electrostatic control may arise is through the non-parallelism of the needle and quadrants. From Fig. 6F, which represents an exaggerated case of this kind, it is clear that a displacement of the needle either to one side or the other causes the pull of the fringe of lines on its front edge to increase and that on its rear edge to diminish, the resultant electrostatic pull on the needle thus tending to increase the displacement. Even in the most carefully constructed instruments perfect parallelism cannot be secured, and therefore a certain amount of negative control must always be present. This can be magnified by suitably manipulating the levelling screws. Schultze* and Scholl† have, in fact, independently shown that in some electrometers it is possible to neutralise entirely the positive electrostatic control and obtain a straight-line sensibility characteristic merely by giving a small tilt to the instrument about an axis parallel to that of the needle in its zero position. But the necessary adjustments to secure this are rather tedious when only the usual levelling screws are available. If, however, electrometers were constructed so as to allow the whole quadrant system to be rotated through a small angle about the axis OO (Fig. 6E), the carrying out of this adjustment would be greatly facilitated, and a straight-line sensibility characteristic over a considerable range of needle potential could readily be secured. At very high potentials, however, owing to the existence of an electrostatic tilting couple, there would be a tendency for the inclination between the needle and the quadrants to increase, with an accompanying increase in the negative control. Thus an electrometer compensated on the " inclined quadrant " principle for low needle potentials would be over-compensated at high potentials and would ultimately become unstable.

Outline of General Theory.—A general electrometer formula which takes into account any want of symmetry as well as any contact potential differences that may exist between the quadrants, or between the needle and the quadrants, may be arrived at by supposing the resultant couple on the needle to be developed in a series of ascending powers of θ, say, $A-B\theta-C\theta^2-$&c. Assuming that the deflection is small, we may, by neglecting squares and higher powers of θ, reduce this expression to two terms only, the first of which, A, may properly be called the deflecting couple, and the second, $B\theta$, the total controlling couple. For equilibrium the resultant couple must be zero giving $\theta=A/B$. In the most general case that can be imagined both A and B are complete quadratic functions of V, V_1 and V_2, the potentials applied respectively to the needle and to the quadrants. Hence we may write as the most general expression for the deflection

$$\theta=\frac{a+\Sigma(bV^2)+\Sigma(cV_1V_2)+\Sigma(dV),}{a'+\Sigma(b'V^2)+\Sigma(c'V_1V_2)+\Sigma(d'V)}$$

where a a', b b', &c., are constants.

In the case of a symmetrical electrometer with V_1 and V_2

* This explains the absence of electrostatic control claimed for the special type of electrometer devised by Blondlot and Curie ("Jour. de Phys." VIII., p. 80, 1889).

OF CALIFORNIA

small, and the contact potential differences negligible, this evidently reduces to

$$\theta = \frac{cV(V_1 - V_2)}{a' + b'V^2},$$

which is the result previously obtained.

Again, in an electrometer in which V_1 and V_2 are not small relatively to V, and in which the contact potential differences are not negligible, it can be shown (*see* Orlich, *loc cit.*, p. 152) that, when certain symmetrical conditions are complied with, the general expression for the deflection takes the form

$$\theta = \frac{(V_1 - V_2 + V_Q)(V - \frac{1}{2}V_1 + V_2 + V_N)}{A + B(V - V_1)(V - V_2) + C(V_1 - V_2)^2},$$

where V_Q and V_N denote respectively the contact potential difference between the quadrants, and between the needle and the quadrants, and A, B, C are constants.

In other cases the exact form taken by the general equation depends on the character of the adjustments, the method of connection, &c., and the values of the several constants which enter into the formula have to be determined experimentally. Orlich has discussed methods of doing this at length in the valuable Paper already alluded to, and he shows, among other things, that in direct-current measurements the effect of any dissymmetry or of any contact potential differences can be eliminated, and correct results obtained, by adopting a certain method of manipulation involving four readings produced by commutating the applied potentials.

In alternating-current measurements, on the other hand, contact potential differences have not to be reckoned with, and, therefore, two readings, obtained by reversing the connections either of the needle or of the quadrants, suffice to give correct results. This remark applies also to the use of the electrometer for measuring alternating-current power; but, as an inspection of the general formula will show, it is essential in this case that the electrostatic control should be negligible.

DISCUSSION ON RAILWAY ELECTRIFICATION.

The following communication has been sent by Mr. Philip Dawson to the Secretary of the Institution of Mechanical Engineers in connection with the discussion on railway electrification which took place at the recent joint meeting of that Institution and the American Society of Mechanical Engineers. An abstract of this discussion appeared in our last issue together with abstracts of the Papers read by Mr. G. Westinghouse, Mr. W. B. Potter and Mr. H. M. Hobart. Elsewhere in the present issue we give abstracts of the Papers by Mr. F. W. Carter and Mr. L. R. Pomeroy, which also deal with the subject of railway electrification.

Mr. Philip Dawson, in his written communication, says: I am very sorry that I was detained at London Bridge, and unable, therefore, to take part in the discussion of the Papers at the summer meeting in London. In consequence of my having only received the proofs of the Papers to be read two days before the meeting, it has been quite impossible for me to check the calculations and data given in the various Papers, and this will, therefore, prevent my making my portion of the discussion of these important subjects as interesting as it might otherwise have been. I will, however, make a few remarks which will practically represent those which I intended to make had it been possible for me to be present.

I will take Mr. Hobart's Paper first. Mr. Hobart assumes that the cost of the distributing system is the same in the single-phase and continuous current. This is quite inadmissible, and both Mr. Potter and Mr. Westinghouse in their contributions to this subject clearly state that the single-phase has the great advantage in having the cheaper distributing system. Mr. Hobart assumes that the output for the alternating current motor equipment is only 6 H.P. per ton in the cost of the Brighton equipments for which I am responsible. This is incorrect, firstly, because the weight of the electrical equipment is 36 tons and not 44 tons as wrongly assumed by Mr. Hobart. Secondly, six motors are quite sufficient to run the schedule time with ease, and, as a matter of fact, have often done so; in any case, it appears to me that the method of reasoning of Mr. Hobart is incorrect and really proves nothing. Mr. Hobart assumes the cost per ton of equipment; all those who have to purchase electrical apparatus know how erroneous such assumptions are. Mr. Hobart further assumes that the cost of electricity delivered to the railway is 0·7d. per B.O.T. unit. This is a great deal too high, and, as a matter of fact, the line with which I am connected will very soon reach a point which will only cost them ½d. per unit on their railway at the periodicity and at the pressure at which we use it. Mr. Hobart in his figures of cost of electrical energy per train-mile assumes that the electricity will cost us from 10d. to 15d. per train-mile; as a matter of fact, on the basis of the energy consumption which now exists and at ½d. per unit, this figure for our service only amounts to 4·83d. per train-mile. In this connection it must also be borne in mind that the South London line is a very bad line for running. It is full of short radii curves, and there is a rising gradient in each direction out to each station with the exception of the termini. Out to Victoria there is a gradient of 1 in 64 for a very considerable distance, and owing to the congested nature of the traffic, practically every train is stopped once or twice by signal both on entering London Bridge and Victoria.

Although I have no time to check Mr. Hobart's calculations, I believe there would be no difficulty in carrying out under the Southport conditions of distance between stations, gradients and curvature the services there running at the present moment with the Brighton equipments. Mr. Hobart's assumptions for charges for rolling stock I am entirely at a loss to understand, or his statement that the cost for electricity, plus individual charges, is 3d. higher for single-phase than for continuous current. I do not wish it to be thought that I am in any way criticising the continuous current, which gives such excellent results, and I think it is a pity that at this stage what amounts to an attempt to decrease the very great advantages possessed by single-phase should be attempted by engineers. In electrifying any portion of a main line railway system it must always be borne in mind that very large extensions may come about in the future, and even Mr. Hobart talks of a 30-mile radius. Under these circumstances it certainly appears to me that the single-phase system cannot be dismissed in the very simple way in which Mr. Hobart has attempted to do it.

Mr. Hobart suggests that the energy consumption on a test run on the train amounted to 79 watt-hours per ton-mile. Whilst these figures were those guaranteed by the manufacturers, the actual tests gave 66 watt-hours per ton-mile. That we have a very large amount of spare power on the trains on the South London line is shown by the fact that under ordinary running conditions it is quite possible to make up two minutes on the schedule run of 24 minutes. There are a great many other figures in Mr. Hobart's Paper which I should like to have taken exception to, and errors which I should like to have corrected, but as already mentioned, I only received the Papers two days before the meeting, and it has, therefore, been quite impossible for me to do this. In any case I think I have shown that Mr. Hobart's conclusions are entirely vitiated by the results obtained on the South London line.

I think Mr. Carter's Paper of great interest, but I should like to point out that the comparison of the cost as instituted by him between the South London and Tynemouth electrifications is entirely misleading, and that had I had to instal the third rail system on the South London line the cost of doing this would have been greater than the single-phase system; in any case, in advising the adoption, which I did in the case of the Brighton Railway, I had to bear in mind possible extensions as far as Brighton, and experience has certainly shown that the adoption of my advice has proved most satisfactory to the Brighton Railway Co.

As regards the very able Papers of Mr. Potter and Mr. Westinghouse, they are so full of figures that I had not time to criticise them very thoroughly. I should, however, like to point out that there is a very great discrepancy between the results obtained by these two eminent authors, who have had such vast experience in America, and who also have had the information and data of two such eminent manufacturing concerns as the Westignhouse Company and the General Electric Co., respectively, for whilst Mr. Westinghouse distinctly proves that the single-phase system is by far the most economical Mr. Potter succeeds in proving the reverse. I think this shows how easy it is to come to a false conclusion, unless every individual case is thoroughly investigated on its own merits by railway engineers. I should like to point out in this connection that the railway engineers of the various German States, Sweden and Switzerland, and many other railway engineers, after the most careful consideration, came to the conclusion that for the electrification of any portion of a main line railway, be it suburban, interurban or long distance, the only really satisfactory system to be employed is the single-phase. I do not give this as my own opinion, but only wish to refer to it as a general impression gaining ground in Europe.

THE WORK OF THE PHYSIKALISCH-TECHNISCHE REICHSANSTALT IN 1909.

(*Continued from p. 639.*)

Self-Induction of Standard Resistances.—A formula for the self-induction coefficients of band resistances was determined similar to that used when measuring large alternating currents, and an electrical method was thought out for comparing these self-induction coefficients by means of high frequency currents. A large number of these resistances from 1 to 0·001 ohm were made, and their self-inductions calculated and measured. The results have been published.

Measurement of Small Alternating Currents.—An instrument fitted with Salomonson bridge connections was built up of constantan-manganin thermo-elements, the wires being only 15μ in diameter, while the smallest wires used up to the present have been 20μ. The most suitable length of an element was found to be about 13μ, and with a total resistance of about 100 ohms each arm of the bridge contained four elements, the thermo-electric power of the instrument being about 16 millivolts when a current of about 6 milliamperes was flowing. By the use of finer wire for the same total resistance there is a reduction in the number of elements, a simplification in the manufacture and a considerable increase in the sensibility being thus obtained.

A difference in the readings given by the instrument on continuous and alternating current occurred, as the resistance of the thermo-element in the neighbourhood of the junction has a considerable temperature coefficient. With continuous current the resistance of the element is, owing to the Peltier effect, different in the two directions, and the method of discharging the bridge galvanometer in the two current directions does not alone give the thermo-electric power of the elements, but is higher by an amount depending on the difference in resistance of the elements in the two directions. Attempts were made to avoid the troublesome reckoning of the difference, first, by a suitable arrangement of the connections and, secondly, by the use of thermo-elements with resistance material of small temperature coefficient.

The first was obtained in the following way: A resistance, A (Fig. 1), which could be short-circuited, was connected in series with the galvanometer G. The resistance was so adjusted with continuous current that the middle reading of the galvanometer was the same as when alternating current of the same effective value was employed and the resistance short-circuited. The percentage difference is, therefore, corrected for the whole scale, as it is a constant value independent of the load. The mean resistance of a thermo-element and of the whole bridge arrangement is, on account of the Peltier effect, higher with continuous than with alternating current. This difference was compensated by connecting a resistance, B, in the main circuit of the instrument, which is short-circuited with a plug when working with continuous current. The same plug, as mentioned above, may be used for the purpose. Two other resistances, C and D, which can be continuously altered, are connected in the galvanometer circuits. One of these is used for the compensation of the temperature coefficients of the sensitiveness of the instrument, and is provided with a scale divided into degrees Centigrade. The other resistance is provided to allow for any decrease in the sensitiveness which may occur in the course of the year, or due to overloads. The galvanometer is provided with a scale of milliamperes. Another resistance, E, is also provided to enable the total resistance of the instrument to be brought to any particular value. The instrument has shown itself to be useful by many repeated tests and researches.

As regards the removal of the temperature coefficient of the resistance in the thermo-elements it appeared best to weld the thin wire instead of to solder it, as all soldering material has a considerable temperature resistance coefficient. An instrument with this description of contacts was supplied by Messrs. Hartmann & Braun. The contact and the mechanical strength of the welded junction was good, the difference being somewhat smaller than in elements soldered with silver and amounting to about 1·1 per cent. The well-known phenomenon of a manganin wire becoming coated with a copper skin when heated was observed, a temperature coefficient of about 0·00015 per degree Centigrade being noted on these occasions. The manganin wire taken from store had only a temperature coefficient of some millionths per degree Centigrade, while the temperature coefficient of constantan wire was of the same value, but negative in direction. The temperature coefficient of constantan is not considerably affected by melting the wire. The copper covering on heated manganin wire can be sometimes washed off with nitric acid.

A clean manganin wire was heated to redness in a high vacuum, and in this case no copper skin appeared and the temperature coefficient remained small. There is, therefore, no danger that an accurate or only slightly inaccurate instrument will become very inaccurate if overloaded. Manganin and constantan can be electrically welded *in vacuo*, so that if elements have an inaccuracy exceeding 10 per cent. they are more than red hot. The phenomenon was not improved by melting the wire in pure hydrogen and thus preventing oxidation.

The difference was finally reduced by performing the welding in the following way. A manganin and constantan wire were twisted about 10 times and their ends were stretched out by two clamped-on screws (*ss*). The twisted part of this "bridge" was hung on two metal strips (*mm*) placed about 0·5 mm. apart (*see* Fig. 2). When a suitable voltage is applied the twisted parts are melted and burnt through. The other wire parts are cooled by dropping water at *ww*, so that immediately two elements are established. In this case the difference is about 5 to 7 per thousand with this arrangement. The melting occurs very accurately, so that a large number of elements can be set up in a short time and with a small expenditure of material. The melting places give good contacts and support a tensile stress quite well.

Standard Capacities and their Absolute Measurement.—Four standard air condensers made up of circular magnalium plates were erected, three being of 0·01 mfd. capacity with 73 plates, having a diameter of 20 cm., and one of 0·03 mfd. capacity with 101 plates, having a diameter of 30 cm. The plates were placed 2 mm. apart. These air condensers, which now have an aggregate capacity of 0·1 mfd., are used for the determination of the absolute value of self-induction standards and for the measurement of energy losses of condensers with solid and fluid dielectric.

These condensers were tested during the year in connection with the newly-constructed rotary interrupter. With the help of the speed indicator described in the 1908 report, the absolute value of capacity standards based on that of the international ohm could be determined with great accuracy, and the results of these measurements, as well as a detailed description of the air condensers, the rotary interrupter and the speed indicator, has been published.

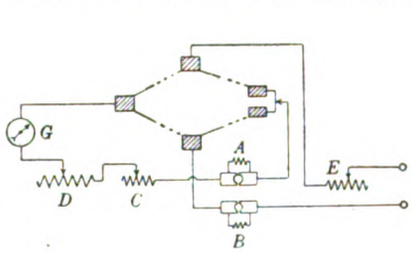

FIG. 1.

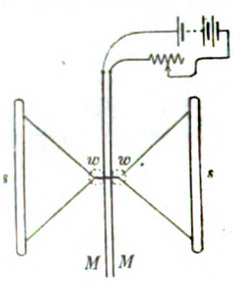

FIG. 2.

The Generation of Alternating Currents of Constant Frequency.—A rectified continuous current obtained by means of a rotating interrupter with a speed regulator is subject to some alteration in frequency during the period of one revolution, and is, therefore, unsuitable after it has been transformed into alternating current for absolute measurement with a slightly damped vibration galvanometer. If, however, it is produced by an electromagnet which is excited by a current having a frequency several times that of the mean interrupter frequency, resonance oscillations are set up and by means of a mercury contact, periodically interrupted direct current whose frequency is free from the oscillations mentioned above is generated. The alternating current mentioned above, generated with the help of this transformer, enables a higher accuracy of measurement to be obtained than was possible hitherto in self-induction and capacity measurements in which the zero position of a vibration galvanometer depends on the frequency.

(*To be continued.*)

PHYSICAL SOCIETY.

At the meeting held at the Imperial College of Science on July 8th, Prof. H. L. CALLENDAR, F.R.S., President, in the chair, a Paper entitled

"The Radio-balance: a Thermoelectric Balance for the Absolute Measurement of Radiation; with applications to Radium and its Emanation,"

was read by the President.

In this apparatus, which was first constructed in 1905, and was briefly described in an article on Radiation contributed to the "Encyclopædia Britannica," heat supplied by radiation is directly compen-

Digitized by Google

sated by the Peltier absorption of heat in a thermo-junction through which a measured electric current is passed. In the simplest form of the instrument, radiation admitted through a measured aperture, 2 mm. diameter, falls on a small copper disc 3 mm. diameter by 0·5 mm. thick, to which two thermo-junctions are attached, forming a Peltier cross. One couple is connected to a sensitive galvanometer for indicating changes of temperature. The other is connected to a battery and rheostat in series with a milliammeter or potentiometer for measuring the current required to reduce the deflection of the galvanometer to zero. If A is the area of the aperture in square centimetres, Q the intensity of the radiation in watts per square centimetre, a the absorption-coefficient of the surface of the disc, P the Peltier coefficient in volts, C the balancing current in amperes, and R the effective resistance of the couple, the equation giving the value of the radiation in absolute measure is $aAQ = PC - C^2R$. The absolute value of P is the product of the absolute temperature by the thermoelectric power. The value of R, in the small correction term for the Joule effect, is readily determined by observing the neutral current, $C_0 = P/R$, for which the Joule effect balances the Peltier effect. In practice two similar discs with similar connections are mounted side by side in a thick copper box, and are balanced against each other in order to avoid changes of zero due to exposure to sunshine, or rapid variations of temperature.

The advantages of the disc radiobalance are that it is very simple to construct and easy to reproduce without material variation in the reduction constants. It is very suitable for measurements of solar radiation, or strong sources, but is insufficiently sensitive for weak sources; and the absorption coefficient a must be determined by comparison with a standard.

In the cup radiobalance, the radiation is received in a copper cup, .. mm. diameter by 10 mm. deep, so that the absorption coefficient is practically equal to unity. Greater sensitiveness is secured by employing a pile of several couples, insulated from the cup, in place of the single balancing couple. External disturbances are eliminated by employing a pair of cups, similarly mounted but oppositely connected, enclosed in a thick copper cylinder. The Joule effect, represented by the C^2R term in the equation, is automatically eliminated by passing the same current in series through the opposing Peltier junctions soldered to the bottom of the cups. The cup exposed to radiation is cooled, and the cup screened from radiation is heated by the Peltier effect, while both are equally heated by the Joule effect. A complete observation involves reversing the current and switching over the radiation screen, in order to eliminate any difference of sensitiveness of the two piles. By observing the neutral current, each cup can be used separately, as with the disc balance, but the disc balance cannot be used with the Peltier couples connected in opposition, unless the balancing couples are insulated from the discs. The cup radiobalance is sensitive to less than a tenth of a microwatt, and is very suitable for measuring the heat evolved by small quantities of radioactive substances.

A Paper entitled

"The Convection of Heat from a Body Cooled by a Stream of Fluid"

was read by Dr. A. RUSSELL.

Attention is directed to certain deductions made by Boussinesq from the mathematical theory of the conduction of heat in liquids. Complete proofs are given of Boussinesq's formulæ, stress being laid on their limitations, and some of their practical applications are pointed out. It is proved that when a hot body is immersed in a stream of liquid flowing with constant velocity, the cooling is proportional to the difference of temperature between the body and the liquid. Newton proved experimentally in 1701 that this law was true for the case of a hot body being cooled by a draught of air. He enunciated his law with reference to the forced convection of heat from a body, and not, as is often stated, to the natural free convection from it. Lorenz has shown that in special cases the natural convection of heat will vary as the 1·25th power of the difference of temperature. Provided that the velocity of the cooling draught is kept constant between certain limits, Compan has shown that Newton's law is very approximately true even when the difference of temperature is as high as 300°C. Another deduction from the formulæ proved in the Paper is that the cooling is very approximately proportional to the square root of the velocity of the convection current. The author gives the solution of the problem of the heating of a liquid flowing steadily, with a velocity less than the critical velocity, through a cylindrical tube which is maintained at constant temperature. It is shown that, in many practical cases, the heating power of the tube varies as $R\theta\sqrt{s\sigma k V l}$, where R is the radius of the tube, θ the difference of temperature between the tube and the liquid, s the specific heat, σ the density, k the conductivity, V the velocity of flow and l the length of the tube.

It is proved that if a wire be immersed in a stream of liquid with its length at right angles to the direction of flow, the electric current which will fuse the wire varies as the 1·25th power of the diameter of the wire. Finally, the effect on the cooling of an electrically-heated cylinder by a stream of liquid, of putting an insulating wrapping round it, is considered. It is shown that in certain cases the effect of this procedure is to lower the temperature of the cylinder, an effect which can be easily demonstrated experimentally. In order to simplify the mathematical work, only the case of incompressible fluids is considered. Experimental results, however, obtained by various physicists are quoted to show that some of the formulæ are approximately true for the cooling of heated bodies by convection with currents of air.

A Paper on

"Hysteresis Loops and Lissajous' Figures, and on the Energy wasted in a Hysteresis Loop."

was read by Prof. S. P. THOMPSON.

Attempts have been made to find an explanation of the forms of the looped curves which express the hysteresis exhibited by iron and steel when subjected to cycles of magnetisation. Physical explanations to account for their general shape have been given by Ewing and Hopkinson, and M. Pierre Weiss has put forward an electronic theory to account for the principal features. The author shows that any hysteresis loop can be analysed into a harmonic series of closed curves corresponding to the various terms in the analysis of the current wave, and their constituents are examined in the Paper. A number of examples of hysteresis loops were chosen and subjected to analysis. The loops chosen related to various kinds of iron and steel, hard and soft, solid and laminated, and taken by various methods. In carrying out the analysis the simple approximate method described by the author ("Proc." Phys. Soc., Vol. XIV.) was used. Details are given of the analysis of various loops, the effect of eddy currents on the size and form of the loops is discussed, and an account is given of the effect of the higher sine and cosine constitutents of the current wave.

Dr. RUSSELL thanked the author for his most interesting and instructive Paper. In connection with Dr. Thompson's orthogonal ellipse, he showed how an indefinite number of two-beaked loops similar to the hysteresis loop could be made up by quadrants of ellipses, each loop having the same height, the same area and the same breadth as the orthogonal ellipse. Two-beaked loops having equal areas, breadths and heights could also be made up from portions of any two curves provided that these curves were similar. He thought it would be of value to discuss the harmonics of the magnetising current, as deduced from the statical hysteresis loop, when the flux varied according to laws other than the harmonic law. F. J. Dykes had investigated the law according to which the flux must vary in order that the magnetising current might have a pure sine shape. To find the harmonics of the flux curve in this case and compare them with the harmonics of the current curve in the author's case would be of interest. A practical use of Dr. Thompson's rapid method of analysing the current wave into its harmonics was that it enabled us to compute approximately the eddy-current losses in iron in certain cases by utilising J. J. Thomson's and Heaviside's formulæ.

Dr. W. H. ECCLES, referring to the emphasis laid by Prof. Thompson on the hysteresis ellipse obtained by his ingenious mode of analysis of the hysteresis loop, suggested that other closed curves would be obtained if other normal functions were used in the analysis. In regard to the author's suggestion that his results affected our notions of the phenomenon called hysteresis, he thought no change was needed if we kept the term to its original meaning of a lag in state, in contra-distinction to (what is often implied) a lag in time.

A Paper entitled

"The Energy Relations of certain Detectors used in Wireless Telegraphy,"

by Dr. W. H. ECCLES, was taken as read.

The Paper is a record of the results of an experimental examination into the physical properties of the electrolytic detector, the zincite rectifier, the carborundum rectifier and a thermoelectric detector consisting of a light contact between graphite and galena. The conditions of the experiments have been generally identical with those arising in the ordinary employment of the detectors, and, in particular, the quantities of energy given to the instruments, in the form of electrical oscillations, have been of the same order in these experiments as in actual practice. Three ways of investigation are followed. The first way consists in applying to the detector an E.M.F. which is gradually increased, and measuring the current at each step. The second way is to fix the E.M.F. at some particular value, to send trains of oscillations of various energy values through the instrument, and to measure the intensity of the sound produced in the telephone on each occasion. The third way is to send trains of constant energy value through the instrument while the steady electromotive applied to it is varied, and to measure at each step the intensity of the sound produced in the telephone. These modes of investigation give curves that may be called respectively the steady current curve, the power curve and the sensitiveness curve. The chief fact brought to light is that the power curves of all the detectors are straight lines, which suggests that all the detectors are fundamentally thermal in their action.

The Rates for Subscription to "THE ELECTRICIAN" are as under:—

	Year.	Half-Year.	Quarter.	
United Kingdom	26s. 0d.	13s. 6d.	7s. 0d.	Post free, payable in advance.
Canada	28s. 3d.	14s. 6d.	7s. 6d.	
Postal Union	30s. 0d.	16s. 0d.	8s. 0d.	

New volumes of "THE ELECTRICIAN" commence in April and October.
(This charge includes all Supplements.)
Vols. I. to LXIV. can now be supplied. Price on application.

"THE ELECTRICIAN" SERIES OF STANDARD ELECTRICAL BOOKS

can be obtained of all Booksellers at Home, in the Colonies, and Abroad.

THE "ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. Published annually in February, corrected to mid-February. Established 1882. A very valuable advertising medium, covering the entire Industry. SUBSCRIPTION Price (which is received *in advance* up to Dec. 31st in each year for the next following edition) 8s. 6d. nett, postage 9d. extra. Published price 15s. nett, postage 9d. extra. Postage to British Colonies, 2s.; Europe, 2s.; U.S.A., 3s. 6d.; other countries, 2s. 6d. *Digest of Contents sent free on application.*

THE "C.T." GEOGRAPHICAL DIRECTORY OF THE U.K. (Electrical Section). Subscription 5s., post free.

"THE ELECTRICIAN" PRIMERS (81 Primers in all, and a GLOSSARY). Single Primers 3d. each post free. *New and Enlarged Edition in One Complete Vol. or Three separate Vols. now ready.* FULL PROSPECTUS FREE.

ELECTRIC TRACTION ON RAILWAYS. By Philip Dawson. Price 25s. nett. *Prospectus free.*

ALTERNATING-CURRENT MOTORS. By Dr. Rudolf Goldschmidt. Price 6s. 6d.

THE SHOT-FIRER'S GUIDE: A Practical Manual on Blasting and the Prevention of Blasting Accidents in Mines, Quarries, &c. By W. Maurice. Price 3s. 6d. nett.

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. Wilkinson, M.I.E.E. *New Edition.* Now ready. Price 15s. nett.

ELECTRIC BLASTING APPARATUS AND EXPLOSIVES: With Special Reference to Colliery Practice. By W. Maurice. Price 8s. 6d. nett.

THE ELECTRIC FURNACE IN IRON AND STEEL PRODUCTION. By John B. C. Kershaw, F.I.C. Price 3s. 6d. nett.

BRAKES FOR TRAMWAY CARS. By H. M. Sayers. Price 3s. 6d. nett.

THE MECHANICAL DESIGN AND CONSTRUCTION OF COMMUTATORS. By R. Livingstone. Price 6s. nett.

THE ALTERNATE-CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Prof. J. A. Fleming, M.A., D.Sc., F.R.S. [abroad 13s.
VOL. I.—Price 12s. 6d. post free, aoroad 13s. VOL. II.—Price 12s. 6d. post free,

HANDBOOK OF THE ELECTRICAL LABORATORY AND TESTING ROOM. Very fully illustrated. By Dr. J. A. Fleming. Vol. I., 12s. 6d. nett, Vol. II., 14s. nett.

ELECTRIC LAMPS AND ELECTRIC LIGHTING. By Prof. J. A. Fleming. 6s. nett.

ELECTRICAL LABORATORY NOTES AND FORMS. Arranged by Dr. J. A. Fleming, M.A., F.R.S. Single copies 4d. nett, or in dozens at 3s. 6d. nett. Complete Sets of 50 Notes and Forms, 12s. 6d. nett, or in strong portfolio, 14s. nett; or bound in strong cloth, 15s. nett. Spare Copies of Tabular Sheets, 1s. per dozen. Portfolios, 1s. 6d. each. Sectional paper, 1s. per dozen sheets. *Complete Prospectus post free on request.*

A SMALLER SET of only 40 Forms, bound strong cloth. Price 7s. 6d. nett.

CENTENARY OF THE ELECTRIC CURRENT—1799–1899. By Prof. J. A. Fleming, F.R.S. Price 1s.; strong cloth 2s. 6d.

ELECTRICITY METERS: THEIR CONSTRUCTION AND MANAGEMENT. By C. H. W. Gerhardi. Profusely illustrated. Price 9s. nett.

ELECTRICITY IN HORTICULTURE. By Prof. S. Lemstrom. Illustrated. 3s. 6d. nett.

RADIO-ACTIVITY: AN ELEMENTARY TREATISE, FROM THE STANDPOINT OF THE DISINTEGRATION THEORY. By Fredk. Soddy, M.A. Fully illustrated. Price 6s. 6d. nett.

ELECTROMAGNETIC THEORY. By Oliver Heaviside. Vol. I. Price 12s. 6d. Vol. II. Price 12s. 6d. *Vol. III. in the press.*

MOTIVE POWER AND GEARING FOR ELECTRICAL MACHINERY. By E. Tremlett Carter, C.E., M.I.E.E. Revised by G. Thomas-Davies, A.M.I.E.E., F.C.S. Price 12s. 6d. nett.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. Ewing, B.Sc., F.R.S., F.R.S.E. Price 10s. 6d.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. Kennelly and H. D. Wilkinson, M.I.E.E. Price 6s. 6d.

ELECTRIC MOTIVE POWER. By Albion T. Snell. Price 10s. 6d. nett.

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. Gelpel and H. M. Kilgour. Price 7s. 6d. nett.

ELECTRICAL TESTING FOR TELEGRAPH ENGINEERS. By J. Elton Young. Price 10s. 6d.

STUDENTS' GUIDE TO SUBMARINE CABLE TESTING. By H. K. C. Fisher and J. C. H. Darby. Price 7s. 6d. nett.

SIGNALLING ACROSS SPACE WITHOUT WIRES: THE WORK OF HERTZ AND HIS SUCCESSORS. With new Chapter on Tuning. By Dr. Sir Oliver J. Lodge. Price 5s. nett.

THE ART OF ELECTROLYTIC SEPARATION OF METALS. By Dr. G. Gore, LL.D., F.R.S. Price 10s. 6d.

ELECTRO-CHEMISTRY. By Dr. George Gore. Price 2s.

BEGINNER'S MANUAL OF SUBMARINE CABLE TESTING AND WORKING. By G. M. Baines. Price 7s. 6d. nett.

CARBON MAKING FOR ALL ELECTRICAL PURPOSES. By Francis Jehl. Price 10s. 6d.

"THE ELECTRICIAN" WIREMAN'S POCKET BOOK. Edited by F. C. Raphael. Price 5s. nett.

"THE ELECTRICIAN" HANDY WIRE TABLES FOR THE POCKET. By P. B. Down, Wh.Ex., A.M.I.Mech.E. Price 2s. 6d. nett.

THE RATING OF ELECTRIC LIGHTING, ELECTRIC TRAMWAY, AND SIMILAR UNDERTAKINGS. By W. G. Bond, M.I.E.E. Price 2s. 6d. nett.

DRUM ARMATURE WINDING AND COMMUTATORS. By F. M. Weymouth. 7s. 6d.

PRIMARY BATTERIES: THEIR CONSTRUCTION AND MANUFACTURE. By W. R. Cooper. Price 10s. 6d. nett.

SECONDARY BATTERIES: THEIR CONSTRUCTION AND MANUFACTURE. By E. J. Wade. Price 10s. 6d. nett.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. Price 1s. 6d.

THE LOCALISATION OF FAULTS IN ELECTRIC LIGHT CABLES. By F. C. Raphael. 7s. 6d.

THE STEAM-ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. Beaumont, M.I.C.E., M.I.M.E., &c. Price 6s. nett.

THE ELECTRIC ARC. By Mrs. Ayrton, M.I.E.E. Price 12s. 6d.

TRAMWAY TRACTIVE EFFORT AND POWER DIAGRAM. By Arnold G. Hansard, B.A., A.M.I.E.E. Price 4s. 6d. nett; in Tube, 5s.

THE BRITISH POST OFFICE TELEPHONE SERVICE. Fully illustrated.. Price 3s. 6d. nett.

INTERNATIONAL TELEGRAPH CONVENTION AND SERVICE REGULATIONS. Price 6s. nett. (LISBON REVISION, 1908.)

BOILER FEED WATER. By F. W. Anderson. Price 6s. nett.

(PRELIMINARY) WIRELESS TELEGRAPH CONFERENCE (BERLIN, 1903), PROCEEDINGS AT. Price 8s. 6d. nett.

INTERNATIONAL WIRELESS TELEGRAPH CONVENTION AND SERVICE REGULATIONS (BERLIN, 1906). With complete report of Proceedings. Price 21s. nett.

THE CLASSIFICATION OF ALTERNATE-CURRENT MOTORS. By V. A. A. Fynn, M.I.E.E. Price 3s. nett.

ELECTRIC CRANES AND HOISTS. By H. H. Broughton. *In Preparation.*

PRACTICAL TELEPHONY. By W. Aitken, M.I.E.E. *In Preparation.*

ELECTRIC MAINS AND DISTRIBUTING SYSTEMS. By J. R. Dick, B.Sc., and F. Fernie, A.M.Inst.C.E. *In Preparation.*

THE PRACTICAL WIRELESS SLIDE RULE. By Dr. H. R. Belcher-Hickman. Price 2s. 6d. nett. *Nearly Ready.*

THE MECHANICAL DESIGN AND CONSTRUCTION OF GENERATORS. By R. Livingstone. *In Preparation.*

LIGHT, RADIATION AND ILLUMINATION. From the German of Paul Högner, by Justus Eck. *In Preparation.*

"THE ELECTRICIAN" INDUSTRIAL SUPPLEMENT.

With "THE ELECTRICIAN" for Sept. 14, 1906, was issued the first of a series of "Industrial Supplements," to be published from time to time with "THE ELECTRICIAN." The fifty-first issue of the Supplement was published (Gratis) with the number of "THE ELECTRICIAN" for July 22.

The "INDUSTRIAL SUPPLEMENT" is a comprehensive record of developments in Electrical Plant, Machinery, Apparatus, Accessories, Sundries and Materials, and of their proved suitability for various Industrial purposes.

MUNICIPAL FINANCE.

Recent events have emphasised the fact that the law relating to municipal corporations is rather complicated and that its intricacies are not understood or appreciated by ordinary laymen, such as those usually elected to municipal bodies in this country. Each session of Parliament sees some addition to the duties and obligations of local authorities, and it is not, therefore, surprising if such authorities occasionally find themselves in awkward positions. As a general rule it may be laid down that a corporation can only contract under seal, and that it can only perform those acts and things which it has been specially authorised to do, while occasionally compliance must be made with rather onerous conditions. This position is sometimes found too rigid by corporations with extensive business departments, such as electricity supply and gas undertakings, tramways, housing schemes, &c., and difficulty is experienced in complying with statutory requirements in such cases.

The position of West Ham, though somewhat exceptional, is a case in point, and members of local authorities and those who have business transactions with local authorities would do well to read carefully the judgment recently delivered by Mr. Justice NEVILLE in an action brought by the ATTORNEY-GENERAL (on the relation of the India Rubber, Gutta Percha & Telegraph Works Co.) against West Ham Corporation. The judgment was set out in full in our last issue. The facts of the case seem to be clear enough, but the position of the defendant Corporation was certainly adversely affected by the tardiness of the Local Government Board in granting sanctions to loans for electricity supply purposes.

Local authorities which possess electricity supply powers are entitled to borrow money for their undertakings on the

Digitized by Google

terms laid down in section 8 of the Electric Lighting Act of 1882, but in doing so they must comply with the conditions set out in the schedule to that Act, and therefore they have to obtain the sanction of the Local Government Board and conform to the conditions laid down in sections 233 and 234 of the Public Health Act of 1875. West Ham Corporation appear to have experienced difficulty in obtaining the necessary sanction to loans for their electricity undertaking, and they therefore resorted to the expedient of an overdraft on their bankers in order to meet current requirements. This overdraft had been running for some years, and at one time it amounted to about £200,000. The India Rubber Co., as large ratepayers in West Ham, had a special interest in seeing that the undertaking of the Corporation was carried on in a prudent, businesslike manner, and naturally were dissatisfied with the loose and illegal method of bankers' overdrafts for financing the undertaking. They therefore brought an action for, amongst other things, a declaration that these overdrafts were unauthorised and illegal and that the Corporation were not entitled to levy a rate for paying off such overdrafts or interest thereon, and also for an order to compel the bank which made the advances to refund all interest already received on this account.

There is ample legal authority for saying that overdrafts, being in fact unauthorised borrowings of money, are *ultra vires*, and, as local authorities are trustees of public money, it is proper to insist that they should comply with the statutory requirements as to borrowing, more especially as these requirements have been made in the public interest. This is all the more necessary nowadays when local authorities have under their control extensive business undertakings, and it is reasonable to expect that they should carry on such undertakings in a businesslike way. If overdrafts were legalised, local authorities could easily evade the provisions which have to be made for repaying the capital expended on work by sinking funds or other means, and municipal accounts would get into a chaotic condition.

It appeared from the evidence in the case that West Ham Corporation had also erred by carrying forward deficits on their electricity undertaking instead of charging them upon, and paying them out of, the local rate as they arose each year, as provided by statute. We are afraid that West Ham is not alone in this respect, but the Local Government Board insist, and rightly so we think, upon provision being made for the payment of accumulated deficits before sanctioning fresh loans. The position of the West Ham electricity department had undoubtedly become very involved, and therefore it is satisfactory to find that the judgment has justified the public-spirited action of the India Rubber Co., who succeeded in obtaining a declaration that the overdrafts were *ultra vires*, and that if the Corporation raised money under borrowing powers they were bound to apply the money so raised to the specific objects for which such loans were sanctioned.

The judgment is not, however, so satisfactory from other standpoints, for the judge expressed the view that there were no means by which his declaration could be enforced; and the transaction may prove an unfortunate one for the bankers who obliged the Corporation with the overdrafts, as they have agreed, without admitting legal liability, to refund £7,000 which had been paid to them as interest. This course may be, and no doubt is, legally correct, but to an ordinary layman it is inequitable and may serve to emphasise the poor opinion of the law held by the average layman. The moral of the case is that those who propose to contract with corporations should first of all ascertain that what they propose to do is authorised by statute or by the common law.

There is, however, another phase of the question. It is becoming more and more apparent that if municipalities take up electricity supply they must be prepared to run such undertakings on commercial lines; they must push the sale of electrical energy and be ready to expand as rapidly as the demand may arise. In such a case as that of West Ham this means that a good deal of money may be required at comparatively short notice and that new plant must be put down without much delay. Now, it is well known that the procedure of the Local Government Board is not characterised by expedition. It may take the greater part of six months to obtain an inquiry, and a similar time before the result of the inquiry is known. If an undertaking is growing rapidly it may be a serious matter to add, say, nine months to the time required to get out plans, call tenders and lay down the plant. Consequently, the moral in this direction is emphatic that the L.G. Board should act in such manner as to facilitate the passing or rejecting of schemes, instead of requiring an absurdly long time in which to decide whether a scheme is, in the view of the Board, satisfactory or not.

REVIEWS.

(Copies of the undermentioned works can be had from THE ELECTRICIAN Office, post free, on receipt of published price, adding 3d. for books published under 2s. Add 10 per cent. for abroad or for foreign books.)

Electrical Installations of Electric Light, Power, Traction and Industrial Electrical Machinery. By RANKIN KENNEDY. Vols. IV. & V. (London: The Caxton Pub. Co.) Pp. viii. + 208; pp. viii. + 223. 7s. 6d. net each.

Vol. IV. opens with the subject of electrolysis. The theoretical sketch includes Grotthus', but not the dissociation, theory. A number of simple experiments as to quantity and quality of deposit are described, and the composition of one or two brassing baths. About a dozen pages are devoted to primary and secondary cells and electric furnaces, but contain little of real value. The author's homopolar machine is again referred to and figured, but we are still left in doubt as to its performance.

We are next switched back again to secondary cells, with descriptions of the principal types, including the Edison cell, which the author considers an important improvement. Electric furnace operations and welding are briefly described, after which a good deal of attention is devoted to thermopiles. Here the author rightly deplores the small amount of information available as to the thermal conductivity of metals and alloys, but considers work in this direction promising of fruitful results. Incidentally, Clamond is systematically given an extra m to his name, and other misprints or errors are somewhat common. In dealing with pyrometers, the Callendar form is quite ignored, but the thermo-junction and Féry radiation patterns are described.

The remainder of the volume is devoted to electric lighting, traction and transmission. Of course, each of these subjects

Digitized by Google

is very sketchily treated, but no important errors are noticeable. One cannot help wondering somewhat at the author's selection of examples, but they, apparently, in many cases are those which have come under his own actual notice.

Vol. V., the last of the series, after dealing with train lighting and rectifiers, is mainly devoted to electric signalling. As to train lighting, the only system described is the Rosenberg cross-excited generator method, and the Stone system is not even mentioned. Rectifiers comprise the Nodon and mercury vapour forms, and the author incidentally introduces us to the Moore vacuum tube lamp. The description of the latter, is however, marred by the inversion of the block, which must leave a neophyte in doubt as to the functioning of the air valve.

A description of two new meters of the author's design is next sandwiched in. They are both of the motor type, the direct-current form resembling the early Chamberlain & Hookham meter, except that the field cuts the disc always in the same sense, and that a separate brake magnet is used. The author claims the latter as a great improvement, giving greater torque, but disregards the advantage of the combined motor and brake magnet in being nearly independent of variations in the strength of the magnet. If greater torque is aimed at, it should be possible to attain this with the additional magnets, without discarding the compensation principle. The alternate-current meter is of the induction type, and does not show any remarkable features.

Dealing next with dielectrics and cables, the author treats us to some remarks on electrostatics, in which we are informed that "when we charge any body we don't put anything into it or upon it, but we set up a field of force represented by radiating lines between it and all surrounding bodies." Apart from the vagueness of this idea, we should like to ask if the author has forgotten his earlier chapter on electrons.

The telegraphic section deals with the batteries and elementary circuits in a fairly clear manner. Why the reader should be told, however, that bridge duplex "works by opposing the P.D. of the batteries" we do not know; and the brevity of some of the descriptions makes them useless to one who is not already familiar with the apparatus. Railway and automatic signalling is fairly satisfactorily dealt with. Telephony is treated in a somewhat unequal manner, the illustrations being poor and exchange connections being given without those of a simple wall set. The KR law is given without any reservation.

A fair amount of space is given to wireless telegraphy. The author's ideas on induction coils, however, seem to be peculiar, and we are given a dissected diagram of a coil of his own design with interchangeable primaries, which may possibly work well in practice, but is certainly not based on sound principles as described in the book. As to wireless telegraphy itself, a few interesting descriptions are given, but a hopelessly garbled mathematical explanation of oscillatory discharges is given on p. 170, and the acoustical analogy is carried to the point of ignoring the transverse character of electromagnetic waves.

On the whole it must be said that, though the present volumes are a considerable improvement on the first edition, and contain much that is interesting and readable, they suffer from the very fault that the author criticises in technical colleges—the attempt to teach too much. If Mr. Rankin Kennedy will give us a few volumes dealing specially with parts of his undoubtedly useful ideas and experience we shall be much more grateful than for his attempt to cover the whole field of electrical engineering. C. V. DRYSDALE.

Alternating-Current Machines. By S. SHELDON, H. MASON and E. HAUSMANN. Vol. II. of "Dynamo-Electric Machinery." Eighth edition. (London: Crosby Lockwood & Son.) Pp. xi. + 353. 12s. net.

This is an American work, better known to English students in the days when electrical books were more scarce than they are at the present time. The new edition has been completely re-written; but, as there is no special preface for it, we assume that that for the seventh edition still holds. In this preface we read that the book has been written as a text-book "for students on other than electrical courses," because of "the growing tendency in many institutions to require more thorough and extended work in electrical subjects from such students." The authors, however, have made the great mistake, common to so many other writers, of trying to put a large amount of matter into a small space. The result is, as it always must be, unsatisfactory, for it can only give a smattering of the subject to any student.

On the other hand, it has several facts and formulæ which are very useful for the electrical engineer's private pocket-book, though this is clearly not the intention of the authors.

Starting with the Table of Contents, as a general rule this is probably the most deceptive part of a treatise of this kind. It may mean anything. For example, the section on the starting of converters might have well occupied several pages; actually it is compressed into a short paragraph.

Chapters I.–IV. are on alternating-current theory, Chapter V. on alternators, Chapter VI. on the transformer; Chapter VII. on motors: (*a*) induction, (*b*) synchronous, (*c*) single-phase commutator; Chapter VIII. on converters, and Chapter IX. on power transmission. Although the list of contents looks very full, yet on the whole the treatment is very superficial.

Several long and complicated formulæ appear for the inductances of various systems without any explanation of how they are obtained, while the derivation of the ordinary E.M.F. formula for an inductive circuit occupies four pages, and is treated very mathematically. And again, although vector diagrams, which are really necessary to the technical man, are passed over very cursorily, yet the theory of complex quantities is treated in such a very mathematical way that it is incomprehensible to the average student. Thus the treatise is very unequal at times.

The idea of giving problems at the end of the chapters is very good, and most of them are just what is wanted, but their utility largely disappears when it is found that the solutions are not given, nor any inkling as to the methods by which the student should tackle them.

The chapter on alternators is very short, but in it space is found to explain the reason of the shape of the saturation curve, which surely students who have advanced so far should be supposed to know.

Magnetic leakage is treated much more fully in the chapter on transformers, and the same method is applied to the slot leakage in induction motors. The tooth-tip, coil-end, &c., leakages, however, are derived more roughly, and several assumptions are made which the student has to take for granted without being shown any justification for them.

To obtain an *approximate* relation between the speed and efficiency of an induction motor, we find that the friction and windage and even all the stator losses are neglected. This is indeed sacrificing accuracy for the sake of simplicity.

The circle diagram is usually a puzzle to the student at first, and it is really very important, yet we can only class the pages devoted to it with those on vector diagrams.

On the whole, the book has several very good points, but we cannot consider it quite suitable as a text-book for alternating-current work at the present time, especially as it is the eighth edition. R. G. J.

POLYPHASE COMMUTATOR MACHINES.*

BY J. JONAS,

Summary.—The author discusses the necessity for and possibility of a polyphase motor with economical speed regulation. This leads to the introduction of the polyphase commutator motor, which is described, and its application in connection with machines of large output explained.

Whilst the development of the single-phase commutator motor has been prominently in the foreground during the last decade, practically little or no progress was made in the polyphase commutator motor; for since the first appearance of the latter motor at the Frankfort Exhibition in 1891 and the Paper by Görges in the "E.T.Z." in the same year, where the importance of the commutator as frequency changer was demonstrated, no important advance was made with these machines for a considerable time.

* Abstract, from the "Electrotechnische Zeitschrift," of a lecture delivered before the Electrotechnische Gesellschaft, Frankfort a.M.

Digitized by Google

At the present time, however, the polyphase motor promises to become an important addition, the reason for this being chiefly the necessity of having a polyphase motor with an economical speed regulation.

Previously, efficiency was often sacrificed for regulation, and the imperfect method of inserting resistance in the rotor circuit was largely adopted. With the advent of machines of large output, however, such as are used for driving rolling mills, winding gears, fans, &c., the question of economy becomes of the utmost importance. But these large outputs were also the chief difficulty militating against the introduction of polyphase commutator motors, for the experience gained with continuous-current machines could not be used directly with these motors. Consequently it was a happy thought that led Krämer to supply only that power to the commutator motor which would otherwise be consumed in rotor resistances. This resulted in the patent D.R.P. 169,453 of the Felten & Guilleaume-Lahmeyerwerke, where a polyphase commutator motor is placed in cascade with the induction motor, and the power supplied to the commutator motor is given back to the shaft (*see* Fig. 5).

Scherbius solved this problem in a similar manner—D.R.P. No. 179,525—whereby the energy taken from the rotor of the asynchronous motor is supplied to an auxiliary commutator motor which drives a generator, so that the energy given out by the latter can be returned to the mains (*see* Fig. 6).

In this way it is possible to regulate the speed of a large motor by means of a comparatively small commutator motor, which has only to take a relatively small part of the total power.

Coming now to the description of the polyphase commutator motor, this machine has a fixed winding consisting of a number of coil-groups corresponding with the number of phases, just like the stator of an ordinary induction motor; these groups of coils being displaced in space by an angle corresponding to the displacement

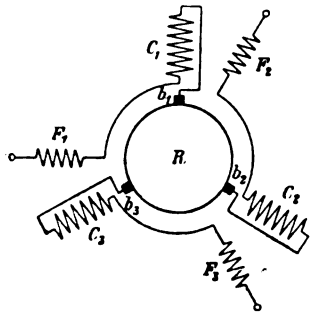

FIG. 1.—THREE-PHASE SERIES MOTOR WITH SEPARATE EXCITING WINDING.

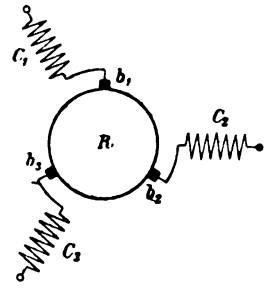

FIG. 2.—THREE-PHASE SERIES MOTOR WITH COMBINED EXCITING AND COMPENSATING WINDING (GÖRGES).

of the several phases from one another; thus, in a three-phase winding, they are separated by 120 deg. The revolving part of the motor is wound like a continuous-current machine and provided with a commutator. It is the commutator which distinguishes this motor from the ordinary induction motor. The difficulty of regulating the speed of induction motors hitherto was that no means were known whereby the low frequency of the rotor currents could be transformed to that of the mains. It was only the knowledge that the commutator always transformed the slip-frequency to that of the motor field—thus to that of the supply—that made this possible, for, since the commutator can be directly connected to the network, energy can be given or taken according to the conditions of working. Thus, whatever the speed of the rotor, the frequency of the pressure at the commutator brushes remains unaltered whilst its value only depends on the speed of the rotor.

We must now see how such a motor derives its torque. Torque is given by the product of field and current, whereby it is assumed these are perpendicular to one another. The field axis is determined by the position of the exciting winding, the current axis by the position of the brushes. Though both winding and brushes are fixed, yet the field and current axes rotate at synchronous speed. Since, however, they always retain the same angle between them, the torque is not affected.

The problem of building a three-phase commutator motor, therefore, falls into two parts; first, the production of the field, secondly, supplying the energy current to the rotor.

Production of the Field.—The field of a polyphase commutator motor is produced by the exciting winding, which is fed by a current or pressure. If the energy current of the motor is used as exciting current, the rotary field produced will not be constant, but will depend on the output of the motor. Thus, if the exciting winding F is connected in series with the energy winding C + R (Fig. 1) the motor will have a series characteristic, the speed being a function of the torque. On the other hand, if the exciting winding F is fed from a constant pressure (Fig. 3) the field will be constant, independent of the load. This motor possesses a shunt characteristic and runs at approximately constant speed. In addition to these, combinations can also be made to give compound characteristics.

It will be presently seen that in addition to the exciting winding there is also a compensating winding C on the stator, and it is possible to combine this with the exciting winding to form a single winding on the stator (*see* Figs. 1 to 4). In a series motor (Fig. 1) the exciting winding F is at 90 deg. to the compensating winding C. The combination of F and C gives a winding somewhat displaced from the brush axis. This is the Görges motor, and is shown in Fig. 2. By varying this angle between the axis of the winding and that of the brushes, the component producing the field can be varied without affecting the series characteristic of the motor.

Likewise an exciting winding fed with constant pressure can be combined with the compensating winding and the rotor winding by supplying the exciting pressure to one of the latter (Fig. 4). The phase of exciting pressure, however, must always be such that the axis of rotary field is always perpendicular to that of the energy current. In Fig. 3, for example, the axes of the exciting and compensating windings coincide, so that the exciting winding would have to be fed from a pressure having the same phase as the motor pressure, in order that the exciting current and flux are displaced 90 deg. from the energy current. In Fig. 4 the exciting pressure is supplied to the compensating winding; this pressure is also the energy pressure.

Supplying the Energy Current to the Rotor.—To supply the motor with energy current, counter E.M.F.s have to be overcome. Of these there are both useful and harmful. Of the useful there is chiefly the back E.M.F. induced in the rotor by rotation in the motor field, for the output of the motor is proportional to the product of this E.M.F.

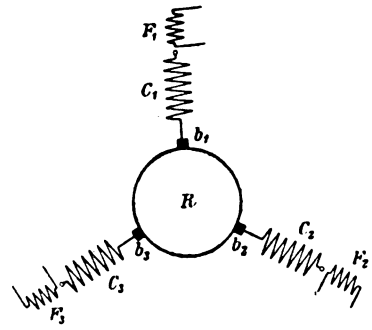

FIG. 3.—THREE-PHASE SEPARATELY EXCITED OR SHUNT MOTOR WITH SEPARATE EXCITING WINDING.

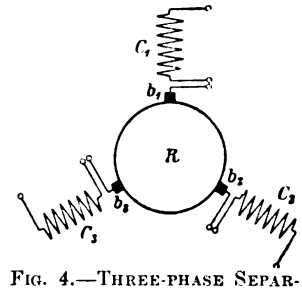

FIG. 4.—THREE-PHASE SEPARATELY EXCITED OR SHUNT MOTOR WITH COMBINED EXCITING AND COMPENSATING WINDING.

and the energy current. On the other hand, the counter E.M.F. of self-induction of the rotor winding is injurious, and can practically prevent any appreciable energy current flowing. It is, therefore, absolutely necessary to neutralise the inductance of the rotor winding along the brush axis and reduce the inductive pressure to a minimum. This is accomplished by means of a compensating winding on the stator, the axis of which is arranged along the brush axis. This winding is traversed by the rotor current or a current proportional to this, and serves to neutralise the armature field (*see* winding C in Figs. 1 to 4), the effective ampere-turns being adjusted to secure this result. The neutralisation of the rotor inductance, however, is not quite so simple as it seems, for in addition to the effective ampere-turns being equal, it is also necessary that the phase of the current in the compensating winding must be such that at every point along the periphery the resultant phase of the compensating winding is the same as that of the armature winding, otherwise local fields will be formed, which make the motor useless. Thus, in a two-phase commutator motor, it is necessary to have either a continuous-current winding for the compensating winding or a winding distributed over the whole circumference, if the rotor inductance is to be completely neutralised. With a three-phase motor this arrangement is not necessary, for in this case the equality of the resultant phases of the two energy windings takes care of itself. Thus we see that the compensating winding is an essential part of the polyphase commutator motor, and the same can either be a separate winding or combined with the exciting winding (*see* Figs. 1 to 4).

Speed Regulation.—It has been mentioned above that a counter E.M.F. is induced in the rotor due to rotation in the motor field. This pressure maintains equilibrium with the pressure supplied to the energy winding, and it is indifferent whether the energy pressure is supplied to the rotor winding or to the compensating winding or

Digitized by Google

to both. For the internal E.M.F. of the rotor is made up of two parts, e_2 being the pressure applied at the brushes and e_i induced in the rotor by the stator field. The counter E.M.F. e_r must maintian equilibrium with the sum of these, *i.e.*, $e_r = e_2 + e_i$ (of course, e_2 and e_i may have negative values).

The speed regulation of the polyphase *series* commutator motor is similar to that in continuous-current machines. Let $e_r = k_1 F_1 n$ and $k'_1 = 1/k_1$, where n = speed, F_1 = motor field and k_1, k'_1 are constants; then $n = k'_1 \frac{e_i + e_2}{F_1}$. For a given definite torque, that is, for a given motor current, n can be adjusted then by either altering $e_i + e_2$, or the flux F_1; $e_i + e_2$ is varied by altering the motor pressure, for example, by means of a variable ratio transformer. The flux F_1 can be varied in motors with separate field windings by varying the number of exciting turns or altering the exciting pressure. In the

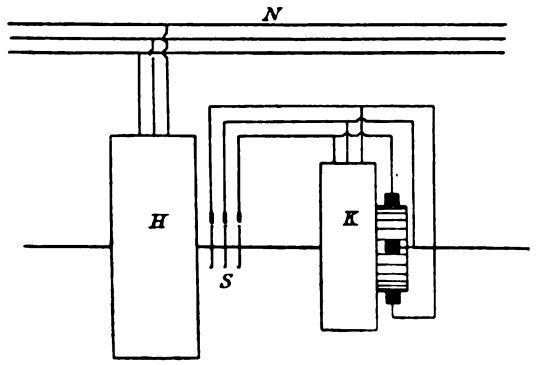

Fig. 5.—Speed Regulation with Auxiliary Motor D.R.P. 169453 (Krämer).

Görges motor, where the windings are combined, the field can be varied by shifting the brushes. In this case, however, the compensating component is also varied, so that the motor will not behave equally well in all positions. To overcome this Osnos proposed using two sets of brushes, one of which is fixed and the other movable.

To regulate the *shunt* motor we have the no-load speed from the relation $e_r = e_i + e_2$ as follows: Dividing the equation by e_i and putting $\frac{e_r}{e_i} = \frac{k_1}{k_2} \frac{F_1}{F_1} \frac{n}{\sim}$, where the ratio k_1/k_2 can be made equal to unity. Then $\frac{e_r}{e_i} = \frac{n}{\sim}$, where n = no-load speed and $\sim$ = synchronous speed. Then $\frac{n}{\sim} = 1 + \frac{e_2}{e_i}$, or $n = \sim\left(1 + \frac{e_2}{e_i}\right)$ is the general expression for the no-load speed of the shunt motor. When $e_2 = o$, *i.e.*, with the brushes short-circuited, $n = \sim$, and the motor runs at synchronous speed.

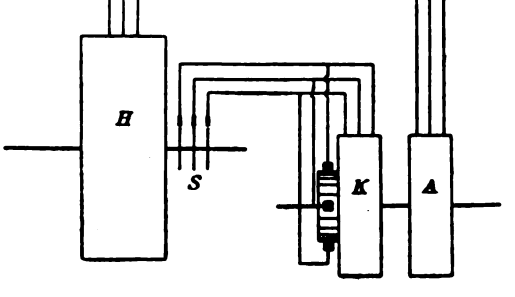

Fig. 6.—Speed Regulation with Auxiliary Converter D.R.P. 179525 (Scherbius).

When $e_i = o$, that is, when the energy pressure is only supplied to the rotor, the flux will be zero and the speed would be ∞. n can now be altered in a variety of ways, for $e_i = e_1 \frac{Z_2}{Z_1} v'_1$, where e_1 is the stator pressure, z_2 the number of energy turns on rotor, z_1 the number of energy turns on stator and v'_1 the resultant leakage coefficient. Hence $n = \sim\left(1 + \frac{e_2}{e_1} \frac{z_1}{z_2} \frac{1}{v'_1}\right)$. Thus the speed can be altered by altering any of these five variables, either singly or together.

Regulation by Means of Auxiliary Motor (Krämer).—This is shown in Fig. 5. The auxiliary commutator motor has only to be dimensioned for the output corresponding to the slip of the main motor. Thus, for a 10 per cent. speed regulation the auxiliary motor has only to be designed for 10 per cent. of the total output. The auxiliary motor is fixed to the same shaft as the main motor, and the latter machine takes entirely the character of the former. If, for example, the commutator motor is a series machine, then the main motor will have a series characteristic, or if a shunt, then a shunt. All the methods for regulating speed can be used with this aggregate and the no-load speed as shunt with this arrangement will be

$$= \frac{\sim}{1 + \frac{p_2}{p_1} \frac{e_2}{e_1} \frac{z_1}{z_2} \frac{1}{v'_1}}$$

where p_1 = number of poles for main motor, p_2 = number of poles for auxiliary motor.

Since the frequency supplied to the commutator motor is always low, it is better to vary $\frac{z_1}{z_2}$ than $\frac{e_2}{e_1}$. With this arrangement the total energy minus the losses is given to the shaft, so that the overall efficiency is very high.

Regulation by Means of Auxiliary Converter (Scherbius).—This arrangement also permits of all the above-mentioned methods of speed regulation being adopted. The polyphase commutator motor, K, (Fig. 6) drives an auxiliary generator, A, which pays back energy to the line. The machine, A, can be either synchronous or asynchronous

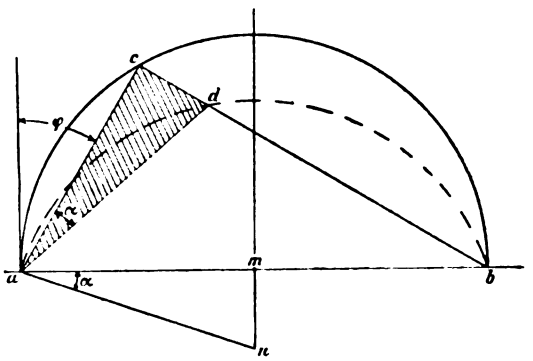

Fig. 7.—Diagram of the Ordinary Polyphase Series Motor.

or a commutator machine. Except in the last case, the speed of the auxiliary set will be approximately constant, being practically the synchronous speed of the auxiliary generator. The no-load speed of the main motor will be

$$n = \left(1 - \frac{\frac{p_2}{p_3}}{1 + \frac{e_2}{e_1} \frac{z_1}{z_2} \frac{1}{v'_1}}\right)$$

where p_2 = number of poles of commutator motor, p_3 = number of poles of the asynchronous or synchronous auxiliary generator.

A disadvantage of this system is that for a given main motor we can only regulate at constant torque, so that the output decreases with the speed. If constant output is required the main motor must be designed for the maximum torque. The efficiency of this arrangement is somewhat lower than that of the former.

For *starting* either of the above arrangements the main motor can be run up to speed independently, as an ordinary induction motor, and afterwards placed in connection with the auxiliary motor.

Sparkless Running.—With a large range of speed regulation the effect of the rotary field on the short-circuited coils (which is a minimum at synchronism) can become considerable, so that it is necessary to have suitable carbons to keep down the short-circuit currents. If these alone are not sufficient there are several other means, amongst which the use of resistance connections between armature winding and commutator and of commutating poles may be mentioned.

Phase Compensation.—Whilst two windings perpendicular to one another have no inductive action on each other in a single-phase motor, in a polyphase motor the relative position of the two windings does not have much effect on the magnitude of the mutual induction. This forms the chief difference between the two types of motor. If both windings are traversed by the same current in the polyphase motor, two rotary fields will be produced having the same angle in

Digitized by Google

space as the windings. If the rotor revolves in both fields, two E.M.F.s will be induced, which are displaced from one another in time by an angle equal to the space angle between the windings.

It is possible, however, to compensate a polyphase motor by means of a leading E.M.F., this E.M.F. being produced by letting the rotor revolve in a field—in addition to the motor field—which leads the motor field by 90 deg. in space. The leading field, however, has the axis of the energy winding and the phase of the energy current and also the sense of the rotor ampere-turns. If then a polyphase motor is under-compensated, so that a flux exists along the energy axis in phase with the energy current, the power factor of the motor is improved. This is seen from the diagram. Fig. 7 shows the method of working of the ordinary uncompensated polyphase commutator series motor. The diagram is developed in the same way as in a single-phase commutator motor.

$ac = i(L_1 + L_s + L_2 - 2M)$,
$cd = i\Sigma\omega$,
$db = e_r$ = counter E.M.F. due to rotation in motor field,
ab = E = applied pressure.

The angle acd is a right angle and the locus for the motor current vector is a circle acb, whose centre lies in the mid point of ab. By dividing all the vectors by $L_1 + L_s + L_2 - 2M$ then ac denotes the motor current directly and $ab = \frac{E}{L_1 + L_s + L_2 - 2M}$ is the ideal short-circuit current of the motor, and

$$\tan\alpha = \frac{cd}{ac} = \frac{\omega}{L_1 + L_2 + L_s - 2M} = \text{constant}.$$

If now a second E.M.F. is induced in the rotor by rotation in a field in the energy axis and proportional to the energy current, we get

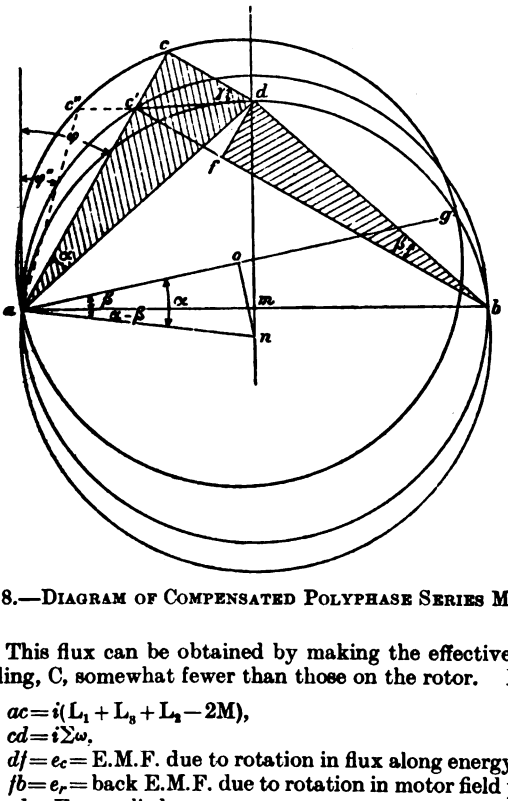

FIG. 8.—DIAGRAM OF COMPENSATED POLYPHASE SERIES MOTOR.

Fig. 8. This flux can be obtained by making the effective turns of the winding, C, somewhat fewer than those on the rotor. In Fig. 8.

$ac = i(L_1 + L_s + L_2 - 2M)$,
$cd = i\Sigma\omega$,
$df = e_c$ = E.M.F. due to rotation in flux along energy axis,
$fb = e_r$ = back E.M.F. due to rotation in motor field proper,
ab = E = applied pressure.

To find the locus of c we first find the locus of d. This point lies on a circle whose chord is ab and angle $adb = 90 - \beta + \alpha$. For

$$\angle adb = \angle adf + \angle fdb = \angle\alpha + 90 - \beta,$$

where $$\tan\alpha = \frac{cd}{ac} = \frac{\omega}{L_1 + L_s + L_2 - 2M} = \text{constant}$$

and $$\tan\beta = \frac{fd}{fb} = \frac{F_H}{F} = \text{constant},$$

where F_H = flux proportional to current along main axis, F = motor flux proper along exciting axis.

Hence $\angle 90 - \beta + \alpha$ is also a constant angle and d lies on a circle whose centre n is the point of intersection of the perpendicular from the centre of ab and the line through a at angle $\alpha - \beta$ to ab. The locus for c is then easily found when it is remembered that the $\triangle adc$ always remains similar, so that ac and ad enclose a constant angle α also ac bears a constant ratio to ad. c then also lies on a circle whose diameter is displaced from the diameter of the d-circle by $\angle\alpha$ and is in the ratio ac/ad. If then we set off ag at $\angle\alpha$ to an to cut the d-circle in g, then ag is the diameter of the c-circle, and the centre o is the point where the perpendicular from n cuts ag. As seen from Fig. 8, for the same input as in Fig. 7, the point c moves to c'' and the $\angle\phi$ to ϕ'', thus improving the power factor.

For the speed n we have

$$\tan\gamma = \frac{l_c}{i\Sigma\omega} = \text{constant}\frac{in}{i} = \text{constant} \cdot n.$$

The power factor of the shunt motor can also be improved by simple means, but this will be further explained in a later article.

THE ELECTRIFICATION OF TRUNK LINES.*

BY L. R. POMEROY.

It is assumed, from a physical and mechanical viewpoint, that electric traction can meet all the demands and requirements of railroad service. Therefore, whether electricity will replace steam traction or not is entirely a commercial problem.

It may be stated at the outset that, whatever system of electrification is adopted, a very large outlay has to be faced, and no case for electrification can be made out unless an increase in net receipts can be secured more than sufficient to pay interest on the extra capital involved. This increase may be brought about either by decreasing the working expenses for the same service, by so modifying the service as to bring in a greater revenue, or by a combination of these. The fundamental principle, based on the present state of the art, seems to be that if you cannot accomplish something by means of electricity that is now impossible by steam traction there is nothing to justify the change; the substitution of one kind of power for another merely to obtain the same result is not commercially warranted. In heavy work the limiting feature of the steam locomotive is the boiler, and the maximum adhesion can be utilised only at low speeds. For example, a 2-8-0 locomotive with 180,000 lb. on the drivers has a tractive force at 10 miles per hour of about 40,000 lb., or 4·5 to 1. At 30 miles per hour the tractive force becomes 13,250 lb., or 13·5 to 1. As tractive force governs the tonnage hauled, the ability of the electric locomotive to utilise almost indefinitely power proportional to the maximum adhesion and produce a drawbar pull entirely independent of the critical speed of a steam locomotive, as limited by the boiler, is a marked feature. In heavy gradient work the ability to increase the speed shows up favourably to the electric locomotive as enlarging the capacity of a given section, but here also the business has to be sufficient to absorb the increase in fixed charges. With steam locomotives a coal consumption, when running, of 4 lb. to 5 lb. per indicated horse-power-hour really means 6 lb. or 7 lb. at the rail, when the losses due to firing up, laying by in yards and sidings, blowing off at the pops, and consumption of the air pumps, are taken into account. Whereas, under electric operation, with an efficiency of 65 to 70 per cent. between the power house and the rail, a coal consumption of 4 lb. per kilowatt-hour at the rail can be counted on. The writer considers 1d. per kilowatt-hour at the rail a conservative figure, and will use this cost in the following computations. The relative difference in the cost of coal at the rail is represented by the following figures:—

Electric power station $\frac{2{\cdot}5 \text{ lb.}}{50\% \text{ eff.}} \times 6\text{s.}$ ..... 30s.
Steam locomotive $7 \times 9\text{s.}$ ..... £3. 3s.

or 50 per cent. in favour of electricity. The following results of the Mersey tunnel operation are pertinent: Under electric operation 1 ton of coal at 9s. yields 2·29 ton-miles at 22½ miles per hour, while with steam 1 ton of coal at 15s. yields 2·21 ton-miles at 17¾ miles per hour. The difference, amounting to 55 per cent., is in favour of the electric operation. On mountain gradients or in heavy freight service, where the boiler of the freight locomotive is forced to the limit, and the boilers are designed for this particular purpose, the showing is still more favourable to the electric side. Especially is this true when the steam locomotive is detained on side tracks for as long a period as it takes to make the run, which is very frequently the case, since under these conditions the cost for fuel becomes a larger proportion of the total operating expense. The cost of a unit of power with the steam locomotive becomes relatively higher under maximum than minimum boiler demands, while with electricity the cost per unit is at a uniform rate, whether working under extreme or light power demands.

* Abstract of a Paper read on July 29th at the joint meeting of the Institution of Mechanical Engineers and the American Society of Mechanical Engineers. An account of the joint discussion on this and other Papers appeared in our last issue.

Digitized by Google

Thus, the cost per 1,000 ton-miles is 4s. 9d. for a 2-8-0 locomotive and 3s. 6d. for an electric locomotive. In this connection an article by Mr. C. L. de Muralt is referred to.

It is claimed that, with electric operation, greater mileage is possible with the electric locomotive and that fewer units are necessary to perform the same service. Great stress is laid on the fact that the ordinary freight locomotive makes only 3,000 miles per month, or 100 miles per day, against which is put forward the ability of the electric locomotive to perform practically continuous service, suggesting the propriety of comparing electric and steam operation on the basis of ton-miles per annum each is able to make, and also the relative weight on driving wheels and not their total weight. The operating efficiency of a steam locomotive in freight service is so low, averaging about 3,000 miles per month, that it is generally thought due to limitations, *per se*, in the locomotive, whereas it is mainly due to operating and traffic conditions, which limitations would apply with equal force to the electric locomotives, so that, barring some increase in speed, the electric locomotive can make no greater mileage than its steam competitor in equivalent service, consequently its splendid ability to perform almost continuous service cannot be realised in practice for reasons aforesaid. The time usefully spent is only 28 per cent. of the whole; 22 per cent. is spent in the shops and 50 at terminal yards, side tracks, &c., ready for use. The only case where electric operation is commercially justified is in congested local passenger situations where the conditions closely approach those of a "moving sidewalk," and the records show that these cases have been profitable only when a large increase in business has been realised.

In the annual report of the P.R.R. (1903) the president states "that the congested condition of your system has brought about a large increase in the ton-mile cost, which for 1903 was 25 per cent. greater than for 1899. In order to prevent the increase in ton-mile cost it is necessary to move freight trains faster in places where traffic is dense, and for such purposes the electric locomotive is most efficient." With steam locomotives the most economical average speed for freight service is 12 to 15 miles per hour, where there is ample track space for the free movement of trains. With a dense traffic this free movement can only be obtained by a higher speed, and, if the large train tonnage be maintained, more horse-power is required of the engine and boiler. It is difficult to increase the size of steam freight locomotives without resorting to the Mallet compound articulated type, and here we have the equivalent of two locomotives in one machine. With the electric locomotive it is possible to develop a much greater horse-power and a large percentage of overload at the time when needed, and do it more economically than with steam. The New York Central electric locomotive has a maximum peak horse-power of 3,000, which is 25 per cent. above normal. This maximum is about double the power which can be obtained from the New York Central standard Atlantic type locomotive. Similar proportions can be obtained for electric freight locomotives, and their size and power are not limited by boiler capacity. If the steam locomotive is capable of developing 30,000 t.f. at the drawbar at 12 miles per hour, or 960 H.P., and it is required to increase the speed of the train to 20 miles per hour and maintain the same tonnage, then 1,600 H.P. will be required, which means the employment of a much larger locomotive or double heading. The advantage of the overload capacity on short mountain gradients or for strategic peaks is one of the strong points in favour of the electric machine, and would make electric operation applicable to special cases rather than a universal substitute, in the broad light of commercial considerations.

The author's conclusion, from this survey of the situation, is that the rapid development of suburban passenger traction by electricity will require large power houses at large cities, and these can gradually be made sufficient for working the line on further stretches in each direction, handling congested terminals, or used where commercially practicable, until it may be desirable to electrify the entire division. Electric operation as compared with steam shows to greatest advantage in urban and suburban passenger service. Here, if multiple unit trains are employed, so that a considerable fraction of the total weight is carried on the driving wheels, thus permitting a high rate of acceleration to be used, a schedule speed quite impracticable in steam operation can be maintained. Moreover, a more frequent service can be given without a proportional increase in expense, whilst in times of light traffic small trains can be run, the energy consumption per train in such service being almost in proportion to the number of coaches. The law of induced travel, however, applies to urban and suburban passenger service, but does not hold for trunk lines, and especially freight service.

In conclusion, a number of examples are given of the financial benefits derived from electrification.

ASSOCIATION OF CONSULTING ENGINEERS.

As the objects of this Association have apparently been somewhat misunderstood in various quarters, the committee have prepared a memorandum setting forth in detail the aims and objects of the Association.

This memorandum we reproduce below :—

OBJECTS OF THE ASSOCIATION OF CONSULTING ENGINEERS.

One of the principal objects of the Association is to secure that municipal and other public works shall be supervised by duly qualified consulting engineers. In order that this may be done, it is necessary to know who is a qualified consulting engineer. There appear to be no means of ascertaining this at the present time. It is hoped that the register of the Association will give this information.

The Association will not be antagonistic to the principle of specialisation, as the intention is to include in the Association all branches of the profession—Civil, Mechanical, Electrical, Gas, and possibly others. It is not suggested that every member should possess a knowledge of all branches, or even more than one. Every member will be as free to specialise as he is now. All that is proposed is that every member shall be a properly trained and qualified engineer, and that he shall be acting solely in a professional capacity—that is, as a consulting engineer.

It is not intended to encroach in any way on the authority of the councils of the leading institutions which deal with the different branches of engineering. In fact, it is hoped that these councils will support the Association as acting in the interests of those of their members who are consultants.

Although the existing institutions are thoroughly representative of the profession of engineering as a whole, their province is to deal with the science and problems of engineering which are of equal interest to all engineers. The Association does not propose to deal with these matters at all, but only with the professional status and conduct of those engineers who have adopted consulting work as their profession, and who represent a comparatively small percentage of the engineering body as a whole.

The bye laws governing professional conduct issued by the Institution of Civil Engineers, and now adopted also by the Institution of Electrical Engineers, require that the members of these institutions when acting in a "professional capacity"—that is, as consulting engineers—shall conform to certain rules. The above institutions can make no distinction between their members, and are, therefore, not able to say to which of their members the rules are applicable. As the rules stand, a member can act in one capacity one day and in another the next. There is, or should be, as clear a distinction between the work of a consulting engineer and that of other members of the engineering profession as there is between the work of a barrister and that of a solicitor in the legal profession. The Association of Consulting Engineers has been formed to define clearly the above distinction. If it succeeds, it is believed that it will be acting in the interests of the existing institutions.

The register of the Association will, it is hoped, form a complete list of the qualified consulting engineers to whom the professional conduct rules above referred to will be applicable at all times. This register will be open to inspection by the authorities responsible for spending public money, as well as to anyone else requiring the advice of a consulting engineer.

The rules of the Association, which are now under consideration, will be based on the professional conduct rules of the Institution of Civil and of Electrical Engineers, to which it is intended to add other rules applicable to consulting engineers only. These rules will be submitted to a general meeting in the autumn. It is hoped that all the leading men in the profession will be willing to give their advice and help, so that nothing may be done that would be detrimental to the interests of the existing institutions or of the public.

At present membership is confined to those who are corporate members of the Institution of Civil Engineers and also of the Institution representing the particular branch of the profession in which they practise. The Institution of Civil Engineers has taken the lead in establishing examinations for admission, and has in many other ways taken great pains to improve the status of the engineering profession. The Association is not prepared at the present time to accept the responsibility of considering the qualifications of engineers other than those mentioned above, but it will no doubt be able to do so in the future, should it receive the support it desires from all members of the profession. A provisional list of members is now being drawn up. This list will be revised after the constitution and rules of the Association have been settled.

Digitized by Google

It is hoped that all consulting engineers in sympathy with the objects of the Association will send their names to the honorary secretary, Mr. A. H. Dykes, of 1, Victoria-street, Westminster, London, S.W., so that notice may be sent to them of the general meeting which will be called in the autumn to consider and decide on the rules and constitution of the Association.

CERTAIN CHARACTERISTICS OF DRY CELLS.*

BY C. F. BURGESS AND C. HAMBUECHEN.

In spite of the fact that 40,000,000 or thereabouts represents the number of dry cells manufactured each year in the United States, little scientific work has been done in the way of making a detailed study of the various individual factors which influence the quality of the cell, if we may judge by the meagre publications. On the other hand, much scientific work has undoubtedly been done, if we may judge by the marked improvements which have been effected in the product. It appears that dry cell manufacturers who are doing the larger part of this work do not feel inclined to discuss analytically dry cell construction.

Perhaps 80 per cent. of the dry cells made and used are of the so-called No. 6 size, being in cylindrical form, the zinc container 6 in. high and 2½ in. in diameter. As far as the cylindrical zinc container is concerned, there is striking uniformity in dimensions and construction, the principal difference being in the thickness of the zinc, which may be found to vary from No. 7 to No. 11 sheet zinc gauge.

All cells employ a carbon rod for the cathode plate. In some forms of cells this rests on the bottom layer of paper, and in others it is raised ½ in. from the bottom. It extends up through a pitch seal, and a brass cap or brass screw attached to the top constitutes the positive terminal of the cell. Some of the carbons used are of smooth cylindrical shape, while others are corrugated or fluted to give greater contact surface to the filling material. Another striking similarity in most of the dry cells is the list of materials which are introduced into the zinc container. Similarity then ceases, and we encounter variations in the quality of the materials, the proportions and in the methods in which the materials are introduced into the container. The writers are unable to refer to published formulæ which are descriptive of the better type of cells at present in use. The following list and proportion of materials may be taken as fairly representing the filling mixture in well-known types of cells: 10 lb. of manganese dioxide, 10 lb. of carbon or graphite, or both, 2 lb. of sal ammoniac, 1 lb. of zinc chloride. Sufficient water is added to give proper amount of electrolyte to the cell, and the most suitable quantity depends upon the dryness of original materials, fineness, quality of paper lining, &c. While these are the essential elements, other materials are frequently added—such as starch or other forms of paste, to improve contact of electrolyte to zinc and promote distribution of action throughout the charge. Mercury is occasionally added to effect amalgamations and prolong life of the zinc.

With the materials as above listed and in the proportions named the resulting cells may be good or they may be practically worthless, depending upon various factors. It is generally believed that purity of materials is the pre-eminent requisite. Commercial conditions, however, prohibit the use of chemically pure materials. The customary specifications for manganese dioxide call for a granulated or powdered material having about 85 per cent. of MnO_2 and less than 1 per cent. of iron. This is a specification which can readily be complied with, and by careful selection and concentration it is possible to get as high as 92 per cent. Physical qualities, porosity and size of grains are likewise important. The amount of available MnO_2 differs according to the chemical test employed, and "available MnO_2" by test may not be the available MnO_2 under the conditions existing in the cell. In storage batteries PbO_2 is an active material only when in suitable contact or proximity to the grid or framework of the positive plate; and MnO_2 in a dry cell is active to a degree, depending upon its contact with the conductive carbon constituting the negative electrode. It is evident that penetration into the interior of a piece of MnO_2 is necessary if the entire mass is to be active; and porosity seems therefore to be important.

Sal ammoniac of a very pure grade is generally employed and in addition to purity, the physical qualities of dryness and freedom from lumps are requisite to ensure proper mixing with the carbon and manganese. The zinc chloride is also required to be of high purity and to be free from iron. Sheet zinc constitutes the anode and serves at the same time as a container. Purity is naturally of importance. The purchaser does not have, however, a variety of grades of zinc to choose from.

*Abstract of a Paper read before the American Electrochemical Society.

This anode makes contact with the electrolyte in the form of paper saturated with solutions of zinc and ammonium chlorides. Ideal conditions call for a corrosion of zinc only in amount equivalent to the current delivered to the external current. Excess of corrosion above this amount is caused by local action, and one of the principal problems in dry cell manufacture is to reduce such local action to a minimum.

There are numerous possible causes of local action—*e.g.*, iron or copper in the zinc, manganese dioxide getting between the paper and the zinc, or inequalities in the zinc itself.
